REPORT

OF THE

COMMISSIONER OF FISHERIES.

DEPARTMENT OF COMMERCE AND LABOR,
BUREAU OF FISHERIES,
Washington, December 6, 1909.

SIR: I have the honor to submit herewith a report of the operations of the Bureau of Fisheries for the fiscal year ended June 30, 1909.

PROPAGATION OF FOOD FISHES.

EXTENT OF THE WORK.

In its important work of stocking the public waters with food fishes, and of furnishing food and game fishes for private streams, lakes, and ponds, the Bureau has followed established methods that have had for their main object the largest results at the minimum cost. The magnitude of the operations necessitates close scrutiny of the details of the expenditures, and it is noteworthy that in the fiscal year 1909 the volume of the fish-cultural work was much larger than ever before, while the available appropriations were not increased. In other words, notwithstanding that labor and materials cost more than formerly, the Government has expended less money in order to produce and plant a definite number of food fishes. This result has been achieved by greater efficiency and zeal on the part of employees and by extension of the fields of operation.

The fish hatcheries operated in 1909 numbered 35 and the subhatcheries, auxiliaries, and egg-collecting stations numbered 84; these were located in 32 States and Territories. The regular hatcheries may be classified as follows with reference to the fisheries propagated: Marine species, 3; river fishes of eastern seaboard, 5; fishes of the Pacific coast, 5; fishes of the Great Lakes, 7; fishes of the interior regions, 15.

In the following table the output of the hatcheries is summarized by species. From the aggregate figures given it will be seen that a new record has been made in the Bureau's fish-cultural work, the total output of 3,107,131,911 fish and eggs being 235,675,000 more than in 1908, the best previous year.

SUMMARY OF DISTRIBUTIONS OF FISH AND EGGS, FISCAL YEAR ENDED JUNE 30, 1909.

Species.	Eggs.	Fry.	Fingerlings, yearlings, and adults.	Total.
Catfish			562,580	562,580
Carp			7,807	7,807
Buffalofish			57,400	57,400
Shad	266,000	57,112,000		57,378,000
Whitefish	142,220,000	277,445,000		419,665,000
Chinook salmon	38,859,265	20,177,286	75,429	59,111,980
Silver salmon	272,000	9,470,925		9,742,925
Blueback salmon	100,000	93,409,496		93,509,496
Humpback salmon		10,000	100	10,100
Steelhead trout	271,468	2,181,413	46,500	2,499,381
Rainbow trout	286,150	292,408	2,026,463	2,605,021
Atlantic salmon		647,790	24,435	672,225
Landlocked salmon	570,000	793,550	237,896	1,601,446
Blackspotted trout	602,820	5,993,943	2,049,395	8,646,158
Loch Leven trout			70,000	70,000
Lake trout	22,806,000	27,188,177	1,345,100	51,339,277
Brook trout	905,000	5,821,322	3,723,489	10,449,811
Sunapee trout		229,736		229,736
Scotch sea trout			47	47
Grayling	350,000	808,000	6,032	1,164,032
Pike			44,200	44,200
Crappie and strawberry bass		62,500	217,355	279,855
Rock bass			51,112	51,112
Warmouth bass			2,278	2,278
Smallmouth black bass		262,674	111,924	374,598
Largemouth black bass		32,500	540,962	573,462
Sunfish			317,888	317,888
Pike perch	457,850,000	187,050,000		644,900,000
Yellow perch	10,000,000	213,610,410	50,873	223,661,283
Striped bass		4,518,000		4,518,000
White perch	24,500,000	318,760,000	2,650	343,262,650
Yellow bass		136,938	1,225	138,163
Smelt	24,700,000	9,400,000		34,100,000
Freshwater drum			25,000	25,000
Cod		153,536,000		153,536,000
Flatfish		786,626,000		786,626,000
Pollock		30,890,000		30,890,000
Lobster		164,509,000		164,509,000
Total	724,558,703	2,370,975,068	11,598,140	3,107,131,911

One of the most noteworthy aspects of the fish-cultural work is the increased interest in the utilization of private or semiprivate waters for rearing food and game fishes. This interest appears in all parts of the country and among all kinds of people and is evidenced by the demands made on the Bureau for desirable fishes for stocking purposes. During the year applications were received for fish for planting in 10,112 different bodies of water, an increase of 25 per cent over 1908 and of more than 400 per cent over 1900.

REVIEW OF OPERATIONS.

In considering the results of the fish-cultural work it should be borne in mind that the conditions which determine success or failure often depend largely on physical and meteorological factors operative during the comparatively short spawning season for the different species. Storms, freshets, drought, abnormal heat and cold, and other natural agencies may render abortive the most thorough preparations and most active efforts at particular stations. The most serious drawbacks, however, are the artificial conditions—dams, lines of nets,

etc.—that prevent the spawning fish from reaching their spawning grounds in adequate numbers.

There was a further marked decrease in the collection of shad eggs and in the resulting output of fry. The lack of success at the stations on the Potomac and Susquehanna rivers can be accounted for only by the absence of protective measures that would insure the arrival of a fair percentage of the migrating fish at the spawning grounds. In sharp contrast to the results in Maryland and Virgina was the record at the North Carolina shad hatchery on Albemarle Sound, where the egg collections were larger than in any previous year except 1901. This outcome is clearly attributable to the workings of the recent law that regulates fishing in the interests of conservation.

The hatching of white perch for the Chesapeake basin was somewhat more extensive than in 1908, while the yellow-perch work in the same region showed a falling off owing to the failure to obtain eggs from the first run of fish on the Susquehanna River, where the season opened much earlier than was expected.

The artificial propagation of the Atlantic salmon at the station near the Penobscot River in Maine was much less successful than formerly. The conditions in this stream are most unfavorable for fish and fish culture, and it is not improbable that the long-continued efforts of the Bureau to maintain the run of salmon in the only remaining salmon stream on our Atlantic coast will prove unavailing.

Very boisterous and wintry weather during November interfered with the daily trips of the Bureau's vessels to the cod-fishing grounds and often prevented the launching of dories containing spawntakers, with the result that the cod operations fell off about 40 per cent as compared with 1908. The Norwegian method of obtaining eggs from brood cod was followed at the Woods Hole (Massachusetts) station on the same scale and with the same success as heretofore. The unprecedentedly large production of winter flounder, or flatfish, was chiefly due to the inauguration of the cultivation of this species at the Boothbay Harbor (Maine) station. The combined output of lobster fry at the three marine stations was about 10 per cent smaller than in the previous year, while the hatching of pollock at the Gloucester (Massachusetts) station was much less extensive.

The output of whitefish, while less than in 1908, was fairly satisfactory. Egg collecting in the Detroit River, one of the most productive fields, was seriously interfered with by extensive government improvements which necessitated much blasting. The take of eggs at the western end of Lake Erie was larger than ever before, and it is thought that the unusual success in this field may have been due to the capture there of fish that under ordinary conditions would have spawned in the Detroit River.

The output of lake trout and pike perch was larger than ever before. An important factor in the collection of lake-trout eggs was the cooperation of fishermen operating gasoline boats, who took the eggs and delivered them free of charge to the Bureau's agents. Favorable weather and the active cooperation of Pennsylvania and Ohio conduced to the unusually large output of pike perch.

The drought seriously affected the collection of salmon eggs in the Pacific States. The run of chinook salmon in the Sacramento River appeared to be as large as usual, and the catch of fish for commercial purposes was good, but owing to low water the fish could not reach their accustomed spawning grounds in the McCloud River and in consequence deposited their eggs below the place where the Bureau had constructed racks for their interception. When the heavy rains finally came, the rack in the McCloud was broken, and three men who were working on the rack throughout the night to keep it free from leaves and other débris were thrown into the raging torrent and miraculously saved from drowning. It is estimated that the fish that had congregated below the rack would have yielded 8,000,000 eggs. The output of chinook salmon was much less than in 1908, as was also that of silver salmon and humpback salmon; but a record was established for the blueback, sockeye, or red salmon, owing to the successful opening of the new hatchery at Afognak (Alaska), whose initial output was over 39,000,000 fish. An experiment with the sockeye which may lead to an important outcome was made on Puget Sound. Five hundred fish caught in traps at Point Roberts and donated to the Bureau by one of the fishing companies were towed in a live-car to an adjacent creek and held for the ripening of their eggs. Sufficient eggs were collected to warrant the belief that it will be possible to propagate large numbers of this most valuable species by impounding in fresh water salmon caught in the commercial fishing.

With regard to the cultivation of the fishes of the interior waters, it may be noted that the season showed a marked increase in the output of catfish, blackspotted trout, and landlocked salmon, the work with the last-named species establishing a record as a result of improved methods at Grand Lake Stream. The production of brook trout from the eggs of wild fish fell off in both New England and Colorado as the result of drought, and, as in previous years, the demands for this fish could be met only by the purchase of large numbers of eggs from private hatcheries. There were no material changes in the distribution of the various other fishes that are regularly handled.

Species whose cultivation was undertaken for the first time in 1909 are the smelt, the white bass, and the yellow bass. The smelt (*Osmerus mordax*) is one of the most popular food fishes of the

New England States, in coast waters, in streams, and in lakes. Preliminary cultural operations in connection with the Green Lake (Maine) station resulted in the collection of 35,610,000 eggs, and from the experience gained it is apparent that artificial propagation may be conducted on a large scale and that the eggs may safely be shipped for long distances. Besides its excellent edible qualities, the smelt is valuable for planting in lakes containing trout and landlocked salmon as a food for those fishes. Experiments in the propagation of the white bass (*Roccus chrysops*) have begun at the Mammoth Spring (Arkansas) station, and the indications are that work on an extensive scale is possible. The yellow bass (*Morone interrupta*) has been successfully handled at the same station, where it has been demonstrated that the fish will reproduce naturally in artificial ponds, and also that the eggs may be taken and fertilized artificially; the incubatory period is five days in a water temperature of 59° F.

The important work of rescuing fishes from the sloughs formed by the overflows of the Mississippi and Illinois rivers has been conducted under favorable conditions. Large numbers of valuable food fishes have been restored to the rivers, and many of the younger fish have been utilized for stocking public and private ponds and streams throughout the country. Operations of a similar nature were undertaken on the Chesapeake and Ohio Canal in the fall of 1908, on the occasion of the annual emptying of the canal. As the water falls the fish that have entered the canal from the river collect in the deeper places, where they would eventually be destroyed; and to these points the Bureau sent seining crews, which collected the fish and transferred them to the adjacent parts of the Potomac. About 75 miles of the canal were thus covered, and 47,674 food fishes, consisting mostly of black bass, crappie, sunfish, rock bass, warmouth bass, catfish, and suckers, were saved. The work, however, was less successful than was anticipated, for the reason that persons living along the line of the canal were permitted to seine on some of the best grounds before the Bureau's men arrived.

CONSTRUCTIONS AND IMPROVEMENTS AT HATCHERIES.

The facilities for lobster culture at the Boothbay Harbor (Maine) station have been greatly increased by the purchase of a site near Pemaquid Harbor and the construction thereon of a lobster pound, in which egg-bearing lobsters may be safely kept pending the hatching season. This will permit the Bureau to collect seed lobsters as opportunity is afforded throughout the year and hold them in large numbers instead of having to depend, as heretofore, on possible collections from fishermen immediately before the hatching season. A noteworthy increase in the output of the station should result from this

improvement. At the hatchery the buildings have been put in good condition, and a substantial coal wharf has been built.

The work at the Green Lake (Maine) station has in the past been seriously interfered with by a lack of convenient means of communication. The station has heretofore been reached only by expensive, unreliable, and generally unsatisfactory boat service. To obviate this difficulty, the construction of a road from the hatchery to the public highway was undertaken and is now well advanced to completion.

Owing to an insufficient water supply at the St. Johnsbury (Vermont) station, trout culture at that place has been restricted. Property at Holden, Vt., has been acquired for the purpose of establishing a trout hatchery to be operated as an auxiliary of the St. Johnsbury station. The tract comprises about 24 acres and appears to have all the requisite conditions.

At the Erwin (Tennessee) station 14.8 acres of land have been purchased in order to straighten the boundary line and eliminate certain objectionable features which impaired the usefulness of the station; and at the Cold Springs (Georgia) station 60,000 square feet of adjoining land, containing a dwelling, have been purchased to meet the growing needs of the hatchery.

The water supply at the Neosho (Missouri) station has been falling off for a number of years, and the operations have been curtailed in consequence. To rectify this a new source of supply was acquired, and a pipe line 12 inches in diameter and 11,800 feet long has been laid to connect it with the station. It is believed that a marked increase in the efficiency of the station will ensue.

The basement of the hatchery at Duluth, Minn., has been enlarged, raised, and equipped with new troughs, so that the capacity of the plant is nearly doubled. The flume and intake crib have been reconstructed and improved.

The pond system at the Mammoth Spring (Arkansas) station has been extensively enlarged and improved. At the Bozeman (Montana), Leadville (Colorado), Manchester (Iowa), White Sulphur Springs (West Virginia), and Wytheville (Virginia) hatcheries only minor expenditures were made from special appropriations, chiefly for repairs to buildings and improvements to water-supply systems.

It was expected that the salmon hatchery at Afognak, Alaska, would be completed during the year, but owing to the rigors of the climate, the difficulties in the way of transporting supplies and materials, and the lack of efficient help, the construction stage is not yet passed, although the hatching of fish has begun. Gratifying progress has been made in building, racks have been put in, a heating plant has been installed, and the work of finishing the hatchery, residence, mess house, quarters, tramway, roads, etc., is proceeding as expeditiously as possible.

At Yes Bay, Alaska, a telephone line has been run between the station and the boat landing, a distance of 17 miles, which will be of great assistance in operating the hatchery and has long been needed. A good foundation for racks, 8 feet wide and 250 feet long, has been made of heavy timbers, plank, rock, and gravel across the river at the lower end of the island.

FISH-CULTURAL RELATIONS WITH FOREIGN COUNTRIES.

For many years the Government of New Zealand has been introducing American fishes into waters originally deficient in desirable food and game fishes. The experiments have been addressed largely to the salmons, trouts, and whitefishes, and the Bureau has made many consignments of the eggs of these fishes to this distant colony. The results of the introduction of the rainbow trout were manifested at an early date, and it has long been known that New Zealand affords the best rainbow-trout fishing to be had anywhere in the world; over 40,000 pounds have been taken by anglers in one season from two small lakes, and the value of this species to the colony for sport and food is becoming greater each year. It is only recently, however, that the outcome of the transplanting of other important species has been seen. From information communicated by the fish commissioner of New Zealand, it appears that the blueback or sockeye salmon has become established in some streams, and that the chinook salmon, resulting from eggs sent from the Bureau's McCloud River station in 1901 and subsequent years, appeared in certain rivers in considerable numbers in 1908 and 1909, and has already become the subject of artificial propagation, 238,000 eggs being collected in 1909.

Dr. Gregory Antipa, inspector-general of fisheries in Roumania, has notified the Bureau of the desire of the Roumanian Government to present to the United States lots of young sturgeon from the Black Sea and Danube, with a view to their cultivation and the ultimate stocking of suitable east-coast rivers therewith. The condition of the sturgeon supply in all parts of the United States is most unsatisfactory, and the commercial extinction of the sturgeon in most streams is only a matter of a short time unless radical protective measures are taken by the various States. The efforts of the Bureau to propagate the native sturgeon on several of the leading rivers have been unfruitful, owing to inability to collect the eggs. The importation of new species is therefore well worthy of a trial. Several of the Roumanian sturgeons are most desirable for their flesh and eggs, and their successful introduction to our waters would prove a great boon.

In response to requests reaching the Bureau through the Department of State, fish ova to the number of 568,150 have been donated to foreign countries, as follows:

Country and species.	Number.	Country and species.	Number.
Argentina:		France:	
Blueback salmon	100,000	Brook trout	10,000
Brook trout	50,000	Lake trout	10,000
Chinook salmon	200,000	Germany:	
Lake trout	50,000	Rainbow trout	16,150
Landlocked salmon	15,000		
Rainbow trout	25,000	Total	568,150
Silver salmon	92,000		

Through the courtesy of the Canadian fishery authorities the Bureau, as heretofore, has maintained at Rossport, Ontario, as an adjunct of the Duluth (Minnesota) hatchery, a station for the collection of eggs of the lake trout.

BIOLOGICAL INQUIRIES AND EXPERIMENTS.

OYSTER INVESTIGATIONS AND SURVEYS.

The field work connected with the oyster-planting experiments in Louisiana was brought to a conclusion in January, 1909, and a full account of the results is in course of preparation for publication. As indicated in a previous report, the Bureau's efforts have met with an unusually prompt commercial response in Barataria Bay, which was totally unproductive of oysters when the work began, in January, 1906. At the end of the first year the experimental beds showed so clearly the feasibility and profitableness of oyster culture that in 1907 there were issued by the State 64 leases, covering 700 acres of barren bottom, and at present there are in force 77 leases, covering 906 acres. None of these private holdings became productive until 1908, but in that year there were shipped to market, from waters that previously had produced nothing, 97,090 bushels of oysters, valued at $59,748. These oysters were of high quality and were in steady demand in New Orleans, where oysters from the natural reefs could hardly be disposed of at one-fourth the price.

As an immediate result of this work, the State received during the year an income that exceeded the amount expended by the Bureau in all the experiments in this section. When the grounds at present under lease become fully productive, and especially when the other available bottom in the bay is acquired for planting purposes, the State's revenue from this source will be largely augmented and the income of the planters will be increased several times. It is gratifying to the Bureau that the zeal with which the people of Louisiana have acted on the information furnished by the Government has resulted in the establishment of a profitable industry among an industrious population of small means.

The experiments in St. Bernard Parish, especially in False-mouth Bay, were equally successful, and thousands of acres there have been shown to be suitable for oyster culture. Owing to the isolated situation of the region, however, the field is less favorable for small operators, and developments will probably be in the hands of persons financially able to take large leases.

Barataria and False-mouth bays alone, though producing nothing when the experiments were undertaken, are capable, if properly utilized, of yielding a quantity of oysters equal to the entire output of Louisiana at the present time.

The oyster-fattening experiments at Lynnhaven Bay, Virginia, have been more satisfactory than in the preceding year, but the quantity of oysters fattened was less than in 1907. The difficulties encountered in this work, which is both commercially important and unique, have been many, and it is evident that some of them are not yet overcome. Nothwithstanding the work of many investigators, both in this country and abroad, knowledge of the feeding conditions of oysters is very imperfect, and it is probable that the present experiments may have to await a more thorough understanding of underlying principles. The development of a certain and effective means whereby oysters can be fattened for the market is of highly practical importance to the oyster industry.

The Bureau has continued the cooperation with the Coast and Geodetic Survey and the Maryland Shellfish Commission in the survey of the oyster beds of Maryland, and the work should be practically completed during the fiscal year 1910. This oyster survey is the largest, most accurate, and most elaborate work of the kind ever undertaken.

In response to the request of the Virginia authorities, the Bureau at the end of the fiscal year entered on a survey of the natural oyster beds of the James River to determine accurately their present conditions and prospects. The location, condition, and administration of these beds has been a matter of controversy ever since the present boundary lines were established, and it is hoped that the work now underway will furnish data for such legislative and administrative action as may be necessary to secure their full value to the State and its citizens.

INVESTIGATION OF FRESH-WATER MUSSELS.

The extensive fishery and the important manufacturing interests dependent on the pearly fresh-water mussels of the Mississippi basin and other regions have induced the Bureau to undertake a comprehensive study of the biology of these mollusks and the physical characters of the waters they inhabit. The investigation is timely because of the serious depletion of the supply owing to the great demand for the shells for button making and to the indiscriminate waste

in hunting for pearls. The streams to which particular attention has been given with reference to the abundance and distribution of the useful mussels are the Mississippi in Iowa and Wisconsin, the Illinois, the Iowa, the Kentucky, the Maumee, the Minnesota, the Ohio, and the Wabash. In this work the Bureau has had the active cooperation of professors in the universities of Iowa, Minnesota, Missouri, and Vermont, and of other educational institutions, as well as persons associated in a practical way with the mussel fishery and pearl-button industry. Experiments in the artificial propagation of mussels have been continued, and a large number of fishes have been infected with larvæ of several species of mussels; through the courtesy of the university authorities this important work, begun in the field in autumn, was conducted during winter and spring in the laboratories of the University of Missouri.

Various available sites in the upper Mississippi basin have been examined with a view to locating the biological laboratory whose establishment was recently authorized by Congress. Among the places visited by representatives of the Bureau were Muscatine, Fairport, Davenport, Clinton, and Comanche, in Iowa; La Crosse, in Wisconsin; Winona and Homer, in Minnesota; Rock Island, in Illinois; and Terre Haute and Vincennes, in Indiana. After a careful consideration of the advantages and disadvantages offered by the different places, a location at Fairport, Iowa, was found to be the most suitable and it has accordingly been secured. The site comprises 60 acres of elevated land directly on the bank of the Mississippi. This station will be devoted to the study of all problems connected with the aquatic fauna of the Mississippi Valley, but it will be particularly concerned with the cultivation and preservation of the mussels in the interests of the pearl-button industry.

EXPERIMENTS IN SPONGE CULTURE.

The Bureau is gratified to announce the successful outcome of experiments in sponge culture in Florida, and will shortly make public a detailed account of the work that has extended over a series of years. The recent progress has been such as to warrant the Bureau in recommending sponge culture as a feasible commercial enterprise, and it is understood that a private company has already been organized to conduct sponge-cultural operations following the methods developed and made known by the Bureau. During the year, sponge cuttings grown at the experimental grounds in Cape Florida Channel have, at the end of twenty-nine months, attained an average weight of about 1.25 ounces, the maximum being nearly 2 ounces and the minimum about 0.75 ounce after perfect cleaning and thorough drying. The growth in Anclote Channel was approximately equal to this, but the cuttings at Soldier Key grew comparatively little. It is evident that factors of environment not yet fully understood have considerable influence on both the quality and the rate of growth of

the sponges; enough, however, is known to justify the belief that under proper state regulation and protection very important economic results must come from utilization of barren grounds for sponge planting, while at the same time the stability of the sponge crop will be assured.

STUDY OF FISH DISEASES.

The Bureau has continued to give attention to the diseases to which fish, particularly when under domestication, are liable, and during the past year has devoted special consideration to the occurrence of cancers and other tumorous growths. Tumors in fish have been known for many years, and the Bureau has from time to time collected specimens of various kinds of tumors from different species of fish. Owing to the activity that has characterized the investigation of cancer during the past ten years, cancer in the lower animals, and in fact in all the vertebrates, becomes a subject of great interest.

Certain types of cancer appear to be more frequent than others in domesticated fish; and cancer of the thyroid gland has been observed at various times in trout and salmon at government and other hatcheries. Of late the disease seems to be on the increase, and the Bureau has undertaken a thorough and systematic investigation of the entire subject of cancer in fish, and to this end has availed itself of the services of the director of the New York State Cancer Laboratory, who will pursue his studies in conjunction with the regular work of that institution. The Forest, Fish, and Game Commission of the State of New York also will cooperate in this work.

The inquiries already made have shown that the subject is very important and will require thorough study covering a considerable period of time. Careful investigation has been made in two localities where the disease is so prevalent as to constitute an epidemic; and the work will be extended so as to include a systematic examination of wild fish in open waters as well as the young and adult fish in government, state, and private hatcheries. At Buffalo, N. Y., where it is proposed to conduct experiments on fishes, arrangements have been made for the installation of two aquaria on the closed-circulation plan, with full provision for refrigeration and aeration of the water. The Bureau is fully alive to the far-reaching importance of this investigation, and will devote every energy and facility at its disposal for the prompt and thorough elucidation of the problems of the cause and prevention of this most serious malady.

OTHER INQUIRIES AND EXPERIMENTS.

It has long been a mooted question whether the steelhead trout and the rainbow trout are different species or the same species with somewhat different habits. A special study of these fish in their home waters has been undertaken. The evidence thus far obtained points to the specific identity of the fish. The question is not without

its practical bearing in fish culture, and the inquiry will soon permit a definite conclusion to be reached.

Studies of the physiology of the Pacific coast salmons have been continued. A field party spent the entire fishing season on the Columbia River, obtaining much information and collecting material for use in laboratory chemical analyses. In conjunction with this inquiry, a large amount of data was gathered relative to the catch of salmon in the wheel fishery.

The systematic examination of the interior waters of the country with reference to their biological and physical characters and to their present and prospective fish life has been continued. This season parties have had under investigation Sebago Lake and connecting waters in Maine, Lake Champlain in Vermont and New York, and certain small lakes in Wisconsin. The work in Wisconsin, as referred to in the report for last year, has been in cooperation with the State Geological and Natural History Survey, and has been addressed particularly to the oxygen content of the water at different depths and its relation to geographic and bathybial distribution of the lake trout, whitefish, cisco, muskallunge, and other fishes. The results already attained have an important bearing on the fish-cultural operations of the Bureau and of the various States.

Since the autumn of 1907 the steamer *Albatross* has been employed in conducting a survey of the fishing grounds and aquatic resources of the Philippine Islands. All parts of the archipelago have been visited, extensive collections have been made, and much information has been obtained regarding the conditions and development of the commercial fisheries, the fish trade, and collateral branches. This work was interrupted for several months while the *Albatross* was taken to Hongkong to undergo extensive repairs to machinery and rigging made necessary by the hard and continuous service to which the vessel had been subjected. The survey will be brought to a close in 1910 and the vessel will return to the United States.

In July, 1908, the schooner *Grampus* was employed for several weeks in investigations pertaining to the animal life of the Gulf Stream off southern New England. Collections were made with surface and deep-sea apparatus, and many soundings and temperature observations were made at various depths.

MARINE BIOLOGICAL LABORATORIES.

The marine biological stations of the Bureau at Woods Hole, Mass., and Beaufort, N. C., primarily established and maintained for study and experimentation in the interests of the fisheries and fish culture, have as usual been resorted to by competent investigators from all parts of the country. While the Bureau provides ample facilities for qualified students and does not attempt to dictate the scope and

character of their researches, it is noteworthy that a large percentage of the men of science who avail themselves of the laboratory privileges are engaged in work having more or less direct relation to practical questions, and in the past year an unusual amount of attention was given to subjects having an immediate economic bearing on the commercial fisheries and the cultivation of marine creatures.

THE FISHING INDUSTRY.

STATISTICS AND METHODS OF THE FISHERIES.

In the spring of 1909 the methods, apparatus, extent, and condition of the shad and alewife fisheries of Chesapeake Bay and tributaries were investigated by the steamer *Fish Hawk* and field agents. Each piece of apparatus set for shad and alewives was located on a chart, and arrangements were made to obtain statistics of the investment, catch, etc., for the season of 1909. The inquiry was still in progress at the close of the fiscal year. The number of pound nets and other fishing appliances in the Chesapeake basin has become so large that the movements of the anadromous fishes to their spawning grounds is seriously interfered with, and both natural and artificial propagation is curtailed to a degree that is most alarming. The downward trend of the fisheries and its cause have been repeatedly pointed out in the Bureau's reports, but the States interested have taken no action in the matter. This inquiry has been made in order to afford authentic data with which to demonstrate the urgent necessity for adequate legislative measures.

The local agents at Boston and Gloucester have collected statistics of the quantity and value of the fish landed at these ports by American fishing vessels. The returns have been published as monthly bulletins and distributed to the trade, and have also been issued as an annual bulletin. These fisheries are very valuable and represent about seven-eighths of the offshore food-fish fisheries of the Atlantic coast of the United States. The elaborate and accurate statistics of the yield have been gathered for a long series of years, and afford an invaluable basis for determining the general condition of the fish supply on the great "banks" off New England, the Canadian maritime provinces, and Newfoundland. From the following table, showing by months and species the quantity and value of the yield of these fisheries, it appears that in the calendar year 1908 there were landed over 6,600 cargoes of fish, having an aggregate weight of 181,465,000 pounds, worth to the fishermen $4,629,000. The receipts were nearly equally divided between the two ports, though at Boston practically the entire yield is landed in a fresh condition, while at Gloucester a very large percentage is salted. Compared with the previous year there is shown an increase of 7,548,000 pounds at Boston and a decrease of 17,654,000 pounds at Gloucester.

[a] Includes herring from Newfoundland (3,534,000 pounds frozen, $94,360, and 8,194,196 pounds salted, $131,298).

The most important of the food fishes taken in the offshore vessel fisheries is the cod, of which 63,447,000 pounds were taken on the Atlantic coast and 14,594,000 pounds on the Pacific coast in 1908, the value of the combined catch being over $2,240,000. In 1904, 1905, and 1906 some large fares of cod were taken with purse seines in the vicinity of Sable Island, but in 1907 this method of capture was not successful, and in 1908 the purse seines gave way to hand lines and trawls.

The haddock fishery continues to have the most improved type of vessels. While the fleet has not increased in number, the tonnage is considerably greater than formerly; and vessels of the newer pattern cruise over more ground than the others and operate double the quantity of fishing gear. Practically the entire haddock catch is landed fresh and is intended for immediate consumption. More than 48,000,000 pounds, with a value of $1,127,000, were taken in 1908, an increase of nearly 7,000,000 pounds and a decrease of $40.000 in value as compared with the previous year.

The catch of pollock for the Boston and Gloucester markets in 1908 fell below that of 1907 by nearly 8,000,000 pounds. The product of fresh and salted fish was 13,500,000 pounds, selling for $152,000. A marked change has occurred in this fishery within a few years. Formerly the fish were taken only with lines, but now a large part of the catch is made with purse seines that are thrown about the schools in shallow water off the New England coast.

The yield of halibut in 1908 was 4,125,000 pounds, valued at $298,000, a very slight decrease as compared with the previous year. Georges Bank has been more actively resorted to for halibut than any other ground off the United States coast, and it continues to be a productive ground. In 1908, however, Bacalieu Bank, lying off the eastern coast of Newfoundland, was a more prolific ground. It covers a large area, and in recent years has been extensively resorted to by our vessels. The catch of halibut on the Pacific coast exceeds that on the Atlantic by several million pounds. In addition to the large quantity taken by American vessels on various grounds in southeastern Alaska, there is a considerable amount caught by Canadian vessels and shipped into the United States.

The available supply of mackerel continues to be small, and the annual catch now is insignificant compared with that twenty-five or thirty years ago. The quantity of salt fish landed in 1908, namely, 21,267 barrels, was about 10,000 barrels less than in 1907, but over 11,000 barrels more than in 1906. The receipts of fresh mackerel were 57,566 barrels, an increase of 1,397 barrels over 1907.

The relative productivity of the fishing grounds lying off the United States coast and off the coasts of Newfoundland and the Canadian provinces is shown in the following table, which gives, by

INVESTIGATION OF THE MACKEREL FISHERY.

Since early times the taking of mackerel has been one of the great high-sea fisheries of the country, but since 1886 the fishery has yielded only a comparatively small percentage of the fish caught for many years immediately preceding. It has not been determined whether the mackerel are now actually scarcer than formerly, whether they have changed their grounds, or whether the fishing methods are such as to disperse the schools and reduce the catch.

The migratory habits of mackerel continue to baffle the skill of the most experienced fishermen. Each season during the past five years a large body of mackerel has appeared off the Cape Shore in June, remaining in those waters about six weeks, then suddenly disappearing, and few fish being seen or taken during the rest of the year. In 1907 and 1908 after the disappearance of this body of fish the seining fleet spent several weeks cruising over the usual grounds with little or no success. These periods of great scarcity occurring

in the middle of the season cause considerable anxiety among fishermen and owners of vessels.

The summer mackerel grounds extend from Block Island to the Strait of Canso. In their search for fish few vessels care to take the risk of being absent from the main body of the fleet more than a day or two at a time. Occasionally individual vessels will cruise in distant localities, but as a rule even the most distant ones keep in touch with the fleet.

Many theories are advanced by fishermen regarding the body of fish that suddenly leaves the coast each year. In the opinion of many fishermen the introduction of purse seines and gill nets has been instrumental in diverting mackerel from their regular course. Formerly it was the custom early in July for a large fleet of vessels fitted with hooks and lines to repair to the Gulf of St. Lawrence, where the fishery was successfully carried on until the latter part of October. The large quantity of toll bait used was no doubt the means of holding the fish on the ground. Mackerel continued to be fairly plentiful in that region until vessels ceased to fish with the apparatus mentioned and employed seines as a method of capture. Shortly after that period mackerel were less plentiful and during the past twenty years few fish have been taken in the Gulf of St. Lawrence. In the last two or three years several vessels have visited that region in the fall for the purpose of testing the ground with toll bait. The result of these experimental trips has led fishermen to believe that if toll bait were freely used it would have a tendency to attract mackerel to all the grounds along the Atlantic coast.

The movements of mackerel during the early part of the season of 1909 were different from those noticed in 1907 and 1908. Usually mackerel are first seen about the middle of March in the vicinity of Cape Hatteras; but this year, owing to the prevailing rough weather on that part of the coast where the fishery is carried on, mackerel were not reported until April 17, and few fish were taken until May 12, when four vessels landed trips in New York, immediately followed by eight other seiners capturing schools off the coast of New Jersey. In the latter part of May, few fish being found on the southern grounds, and those sighted hard to catch, the seining fleet fitted for the Cape Shore, where mackerel had been reported. A few hauls were made off that coast on June 7, and fairly good fishing was experienced for about two weeks, after which time the schools of fish suddenly disappeared. This caused most of the fleet to again visit the southern grounds, where fishing was continued until the latter part of June.

Ordinarily the vessels that carry seines capture a great many more mackerel than those fitted with gill nets, but this season, since the mackerel did not appear at the surface as in previous years, the

netters did exceptionally well and landed nearly as many fish as the seining fleet.

In the spring of 1909, at the special solicitation of the Board of Trade and the Master Mariners' Association of Gloucester, Mass., the Bureau undertook an investigation of the mackerel in the interests of the fishing industry. The auxiliary schooner *Grampus* was detailed for the purpose, and an experienced mackerel fisherman was placed in charge of the inquiry, which began in April and was in progress at the close of the year. One of the main objects of the inquiry is to locate the body of fish supposed to be on grounds remote from those cruised over by the seining fleet. The apparatus for locating and making experimental catches of fish consists of gill nets and lines; tow nets are also carried for the purpose of detecting the presence of the minute crustaceans upon which mackerel chiefly subsist. The cruising will extend from Cape Henry northward along the coast to the Gulf of St. Lawrence and Labrador. The work, so far, has been chiefly on offshore grounds from Cape Henry to Cape Cod.

ALASKA SALMON SERVICE.

In the annual inspection of the salmon fisheries of Alaska, the agents visited practically all the fishing centers with the exception of arctic Alaska and parts of western and central Alaska, and obtained information regarding the condition and extent of all the other fisheries of the Territory in addition to the salmon. The agents' detailed report on the fishing industry was published in April, 1909.

The salmon fisheries in 1908 were more extensive and valuable than ever before. In taking the catch and preparing and transporting the canned, pickled, fresh, and frozen fish, 12,183 persons were employed and $9,298,800, exclusive of cash capital, were invested, and the value of the output was $10,683,051. The total quantity of salmon taken was 198,952,814 pounds, of which 125,790,470 pounds represented red salmon, 48,029,055 pounds humpbacks, 15,578,570 pounds dog salmon, 5,291,200 pounds coho or silver salmon, and 4,263,519 pounds king salmon.

Fifty canneries and 40 salting establishments were operated, and the quantity of salmon therein utilized was larger than ever before. The pack of canned salmon was 2,618,048 cases, equivalent to 2,606,972 standard cases of 48 one-pound cans each, and the salmon and salmon bellies salted aggregated 35,949 barrels and 6,247 half barrels.

In southeast Alaska it was found that trap-net fishermen in some localities were openly violating the law by failing to observe the close season, and this too at a time when the canneries were glutted and unable to handle the legitimate catch. Violations to the number

of 53 were reported to the grand jury, which brought in a true bill in each instance, and the cases were tried in the district court at Skagway. The owners of the traps agreed to assume responsibility for the actions of their employees, and plead guilty, whereupon the court imposed a fine of $150 in each case. There is a healthy public sentiment in favor of the strict enforcement of laws for the protection of the salmon, and this sentiment is shared by a very large proportion of the firms and companies having money invested in the fisheries.

In the pickling of salmon bellies, there has always been a very large waste, as the muscular tissue constituting the belly, the only part utilized, represents only a small fraction of the total flesh. This waste, which has amounted to several million pounds annually, appeared to be unjustifiable, and was accordingly brought to the attention of the Secretary of Commerce and Labor with a recommendation that the practice be prohibited. The waste was held to be in violation of existing law, and its interdiction was set forth in the following circular notice to all packers of salmon in Alaska, issued by the Commissioner of Fisheries under date of April 18, 1908, and affecting the season of 1909:

It is desired to call the attention of all packers of salmon in Alaska to section 8 of the act for the protection of the fisheries of Alaska, approved June 26, 1906, which reads as follows:

"SEC. 8. That it shall be unlawful for any person, company, or corporation wantonly to waste or destroy salmon or other food fishes taken or caught in any of the waters of Alaska."

The present methods of preparing the bellies of salmon for the market involve the waste of a large part of the edible portion of the fish. It is believed that this waste is contrary to the spirit and letter of the above provision. The Secretary of Commerce and Labor, who is charged with the enforcement of the Alaska fisheries act, has notified this Bureau that the practice of curing and preserving the so-called belly of the salmon, which results in the waste of a large proportion of the edible portion of the fish, is a wanton waste within the meaning of section 8 above, and that after January 1, 1909, those who engage in this practice will be reported for prosecution, as provided for in the act.

Complaints have reached the Bureau from salmon fishermen in southeast Alaska relative to injury done to the fisheries by the discharge of sawdust and other sawmill refuse into waters where salmon run. Such materials are generally recognized as harmful to fish and fishing, and are the subjects of special laws in many States, but there is nothing in the Alaskan code to cover the case. In order to guard against the pollution of the streams and other waters of the Territory by all kinds of industrial wastes, it is desirable that proper legislation be enacted by Congress at an early date. It will be easier to keep the public waters free from noxious discharges by anticipating the industrial development than by attempting to abate nuisances after they have become established.

Nushagak and Wood rivers, in western Alaska, were closed to commercial fishing by an order of the Secretary of Commerce and Labor dated December 19, 1907, and first effective during the season of 1908. The order was as follows:

A hearing having been given at the Department of Commerce and Labor, beginning December 16, 1907, at which all persons interested in the closing or nonclosing of Wood and Nushagak rivers, Alaska, for fishing purposes were fully heard, due notice of which was given according to law, by virtue of the authority vested in me by section 6 of "An act for the protection and regulation of the fisheries of Alaska," approved June 26, 1906, it is hereby ordered that until further notice Wood River, a tributary of Nushagak Bay, in the district of Alaska, and the region within 500 yards of the mouth of said Wood River be closed to all commercial fishing, and that all commercial fishing be prohibited in Nushagak River proper.

This order becomes effective January 1, 1908.

The presence of the salmon agent in the region of Wood and Nushagak rivers for the purpose of enforcing the foregoing order made possible an experimental count of red salmon on a scale and in a manner never before attempted. In conjunction with the Alaska Packers' Association of San Francisco and the Alaska-Portland Packers' Association of Portland, the Bureau of Fisheries placed a rack across the foot of Lake Aleknagik, the first of the Wood River series of lakes. and provided this rack with tunnels or gates through which the migrating salmon had to pass to reach their spawning grounds. A daily tally was kept, and a count of the entire run was obtained in such a way as to give a figure that may be accepted as very close approximation to the actual number. A few hundred fish passed up before July 1 and several thousand during the first ten days in August, but the height of the run was from July 7 to July 29. On July 14 over 402,000 fish were counted and on the next day over 324,000. The total tally was 2,603,655 fish, which escaped the very active fishing in Nushagak Bay; in addition to these several million fish are known to have ascended other tributaries of Nushagak Bay to their spawning grounds. From the data at hand it appears that the maximum number of red salmon that entered Nushagak basin in 1908 was 13,600,000 and the minimum number was not less than 10,100,000, of which 6,400,000 fish were caught and utilized at the local canneries. Therefore under the most favorable conditions for reproduction, 52.9 per cent of the run escaped, and under the most unfavorable, 36.6 per cent. It is the intention to continue this experimental counting of salmon in the expectation that accurate data may be obtained relative to the natural increment of the fish, so that, knowing the approximate size of the run, the minimum number necessary to maintain the supply may be allowed to escape and the remainder placed at the disposal of the fishermen.

Seven salmon hatcheries operated in 1908–9 handled 176,407,000 eggs, of which number 96,397,000 were incubated at the two government hatcheries at Yes Bay and Afognak. The fry produced by the five private hatcheries numbered 74,249,750 and by the government hatcheries 87,998,770, a total of 162,248,520. Larger results are anticipated when the new station at Afognak is fully equipped.

Other important fisheries of Alaska are the cod, halibut, herring, whale, and fur seal. A number of hitherto minor products are receiving more attention each year, and in a short time will doubtless add materially to the value of the fisheries; in 1908 flounders, pollock, rock cod, and whitefish appeared in the returns for the first time. The extent of the entire fishing industry of Alaska, as determined by the salmon agents, was as follows: Persons engaged, 13,337; investment, $10,319,784; value of products, $11,847,443.

ALASKAN FUR-SEAL SERVICE.

On the establishment of the Department of Commerce and Labor, in 1903, the Alaskan fur-seal service was transferred thereto from the Department of the Treasury, to which it had been attached for many years. In the Department of Commerce and Labor this service formed a distinct branch and was administered through the Secretary's Office until December 28, 1908, when it was transferred to the Bureau of Fisheries. The Commissioner of Fisheries has appointed a special board, composed of five members of the Bureau's staff who have personal knowledge of the Alaskan fur seals, and to this board will be assigned for consideration and recommendation all matters pertaining to the seal life on the Pribilof Islands, the blue foxes, and other animal resources on the islands, and the Government's relations to the natives and the lessees. On January 13, 1909, the Secretary, on the recommendation of the Commissioner, appointed an advisory board for the fur-seal service, consisting of Dr. David Starr Jordan, Dr. Leonhard Stejneger, Dr. C. Hart Merriam, Mr. Frederic A. Lucas, Hon. Edwin W. Sims, Hon. Frank H. Hitchcock, and Mr. Charles H. Townsend. The Government is thus enabled to avail itself of the expert knowledge possessed by these naturalists and officials, who, through visits to the seal islands and through previous duty on fur-seal commissions or in the administration of the fur-seal service, are familiar with the problems involved in the management of the seal herd and the seal islands.

From the report of the agent at the seal fisheries it appears that during the season which closed July 31, 1909, the lessees were unable to obtain the quota of 15,000 skins, for the reason that the requisite number of bachelor seals did not appear in the drives during the legal season. The total take of skins was 14,336, of which 11,022 came from St. Paul Island and 3,314 from St. George Island.

Statistics of the seals driven for killing show that on the two islands 31 and 37 per cent, respectively, of the drives were released as being too large, too small, or marked for breeders. There was a noteworthy scarcity of very small seals in the drives, even late in the season when the yearlings are expected to come in numbers.

The quota of bachelor seals to be preserved for breeding purposes was marked and released during the last week in June. The number was 2,000, half of them being 2 years old and half 3 years old.

A count of the breeding bulls between July 13 and 16 showed 1,071 with harems on St. Paul Island and 267 with harems on St. George Island, and 422 others on both islands. The average number of cows per harem was ascertained to be 42.1 on St. Paul and 34.7 on St. George.

During the season a special count of the seal herd was made by Mr. George A. Clark, a member of the fur-seal commission of 1896–97, to whom was assigned the detailed study of the rookeries in those years. His investigations in 1909, following the same methods and having the same scope, are particularly interesting and important. It appears that the fur-seal herd has undergone a heavy decline during the past thirteen seasons, as evidenced by the fact that in 1896 and 1897 there were 157,000 and 130,000 breeding females, while in 1909 there were only 50,000. This decline has been caused by the continuance of pelagic sealing, which results in the killing of the females in excess of the natural increment of young breeders. The injurious effects of pelagic sealing have greatly increased in recent years owing to the presence of a large fleet of Japanese vessels using firearms and operating throughout the season in close proximity to the rookeries, sometimes forming a close cordon through which the seals have had to pass on their way from and to the rookeries.

The fur-seal service has come under the jurisdiction of the Bureau at a time when the condition of the seal herd is worse than ever before, when the outlook is most discouraging, and when the contract for the lease of the islands for a period of twenty years must, under the law, be renewed. Under the existing circumstances the value of the franchise is greatly diminished, large financial losses may be sustained by the Government, and the perpetuity of the herd is seriously menaced. For many years the precarious condition of the fur-seal herd has been constantly brought to the attention of the Government by various persons well qualified to present the matter, and every authority has forcefully pointed out the immediate necessity of the Government's concluding some arrangement by which the slaughter of seals when away from the islands in search of food should be prevented. The net outcome of the work, arguments, recommendations, and pleas of a long procession of special commis-

sioners, experts, and agents has been (1) the passage of a law by which American fishermen are prohibited from engaging in pelagic sealing while fishermen of all other nationalities are permitted to do so, and (2) the steady and rapid decimation of the herd, which has occurred entirely independently of the legitimate operations on the islands.

If pelagic sealing could have been stopped in 1897, the seal herd to-day would contain 300,000 breeding cows (as against 50,000, the number for the season of 1909), and the product of the hauling grounds would have risen to 50,000 skins, yielding a government revenue of $500,000, as against less than 15,000 skins and a government revenue of $143,000 for the present year. Without the drain of pelagic sealing the herd would continue to increase almost indefinitely.

The Alaskan fur seals constitute the most valuable fishery resource that any government in the world ever possessed. It is little less than a national disgrace that the herd of four to six million seals which came into our possession when Alaska was acquired from Russia and has been under our charge ever since should have been allowed to dwindle until to-day it numbers less than 150,000 of all ages. The mildest way in which to characterize the dissipation of this great source of wealth to our people and of revenue to our Government is that it is a serious indictment of our business capacity. The extent of our loss may be partially seen when it is stated that the failure to maintain the seal herd has during the last thirteen years resulted in a net loss of revenue of not less than $1,600,000, has permitted nearly 300,000 fur seals, having a market value of over $5,700,000, to be appropriated by aliens, and has encouraged those nefarious pelagic operations by which additional fur seals having a value of at least $5,000,000 have been killed at sea, but not recovered; while through the slaughter of breeding females their pups—on the islands, unborn, and prospective—with a potential value of fully $20,000,000, have been sacrificed and wasted.

It is most essential to the interests of this Government and the welfare of the fur-seal herd that appropriate action be taken at once looking to the prohibition of pelagic sealing by subjects of the countries most concerned; and recommendations to this end already submitted to the Department are now renewed and strongly urged.

MISCELLANEOUS ACTIVITIES.

COOPERATION WITH THE STATES.

Active cooperation with the various States in fish-cultural and fishery work has been a feature of the Bureau's policy for many years. This cooperation in the interests of the public welfare will

continue and become more effective so far as the resources and functions of the Bureau will permit.

It is noted with regret that there is a desire on the part of some States to control, curtail, restrict, and handicap, by legislative action or official regulation, the work of the Bureau in artificial propagation; and it may become necessary to resort to the courts to determine the status and rights of federal fish-culture in state and interstate waters in pursuance of acts of Congress. One of the latest exhibitions of this attitude of certain States is the case of Michigan, whose legislature has taken entirely out of the Bureau's hands the collection of eggs of the commercial fishes of the Great Lakes. No necessity for such a course was shown, and the action of the State was in opposition to the expressed wishes of the Bureau and inimical to the interests of fish preservation.

Allotments aggregating 713,391,265 fertilized fish eggs were made by the Bureau to the fish commissions of the various States, as follows:

ALLOTMENTS OF FISH EGGS TO STATE FISH COMMISSIONS, FISCAL YEAR ENDED JUNE 30, 1909.[a]

State and species.	Eggs.	State and species.	Eggs.
California:		New York—Continued.	
Chinook salmon	32,039,265	Landlocked salmon	30,000
Connecticut:		Rainbow trout	20,000
Lake trout	300,000	Blackspotted trout	25,000
Brook trout	30,000	Ohio:	
White perch	5,000,000	Pike perch	158,725,000
Yellow perch	10,000,000	Whitefish	55,548,000
Illinois:		Oregon:	
Rainbow trout	50,000	Chinook salmon	6,581,000
Whitefish	7,000,000	Brook trout	310,000
Pike perch	25,000,000	Blackspotted trout	100,000
Maine:		Steelhead trout	50,000
Landlocked salmon	300,000	Pennsylvania:	
Brook trout	300,000	Pike perch	223,125,000
Maryland:		Lake trout	3,000,000
Rainbow trout	50,000	Blackspotted trout	25,000
White perch	2,000,000	Silver salmon	75,000
Massachusetts:		Whitefish	58,572,000
Rainbow trout	50,000	Vermont:	
Michigan:		Lake trout	400,000
Landlocked salmon	30,000	Washington:	
Lake trout	3,500,000	Steelhead trout	50,000
Pike perch	50,000,000	Wisconsin:	
Smelt	22,500,000	Lake trout	12,125,000
Nevada:		Whitefish	20,000,000
Steelhead trout	50,000	Wyoming:	
New Hampshire:		Grayling	350,000
Silver salmon	50,000	Brook trout	50,000
Landlocked salmon	50,000	Blackspotted trout	210,000
Lake trout	300,000	Landlocked salmon	10,000
New York:		Steelhead trout	60,000
White perch	12,350,000		
Lake trout	3,000,000		

[a] Also there were allotted to California 765 crappie and strawberry bass, 3,600 bream, and 240 yellow-perch fingerlings, yearlings, and adults; to Colorado, 50,000 blackspotted-trout fry; to Minnesota, 4,420 crappie and strawberry bass and 816 largemouth black bass fingerlings, yearlings, and adults; and to New York, 200,000 brook-trout fry.

In the collection of whitefish and pike-perch eggs on Lake Erie the Bureau had the active cooperation of the Ohio and Pennsylvania fish commissions.

An act of Congress approved March 4, 1909, and effective on that date, authorized and directed the Secretary of Commerce and Labor, on the request of the governor of the State of North Carolina, to designate assistants of the Bureau of Fisheries and Coast and Geodetic Survey to cooperate with the Fish Commissioner of North Carolina in surveying and marking the fishing grounds of the State. Cooperation of a similar nature had been given by the Bureau on several occasions, but owing to the more elaborate character of the survey now required by the State and the more permanent nature of the marks to be placed on the fishing grounds, it was thought that specific authority should be obtained from Congress, that the assistance of the Coast and Geodetic Survey should be invoked, and that an appropriation covering the cost of the work should be provided. As the act carried no appropriation, it has been impossible for the Bureau to proceed in the matter.

RELATIONS WITH OTHER GOVERNMENT BUREAUS.

At the request of the Bureau of the Census, four agents of the Bureau of Fisheries were detailed to assist in the taking of a fishery census for the calendar year 1908, and in continuation of the understanding between the two Bureaus no general statistical work was done by this Bureau during the year.

The food and drug board of the Department of Agriculture has submitted to the Bureau from time to time samples of fishery products for identification and for expert opinion as to their proper labeling under the food and drug law. Members of the Bureau's staff have attended hearings before the board and given testimony in fishery cases.

The Bureau of Chemistry of the Department of Agriculture has courteously made analyses of samples of water from the various hatcheries. The object of these analyses is to show the special qualities as to gaseous and mineral content of the fish-cultural waters, and the correlation of the chemical properties with the growth and health of the fish.

The question of stocking with food and game fishes the reservoirs and lakes formed in connection with government irrigation and reclamation projects has been brought up at various times. A conspicuous case is that of the Roosevelt Dam in Salt River, Arizona, which will develop an artificial lake from 10 to 25 miles long and 70 to 220 feet deep. The lake will be near the center of the territory and a long distance from any supply of fish. The Department of the Interior has expressed a desire to have the Bureau stock this lake with fish for the benefit of the people, and the Bureau has agreed to undertake this work. The Government is the owner in fee of all lands covered by the lake, and the lands immediately surrounding have been set

apart as a government bird preserve. These conditions should result in federal surveillance and control.

The Bureau will undertake to stock all such reservoirs with suitable fish and to maintain the supply of fish therein, but it is thought that a definite policy should be determined on for the exercise of proper control over the fishing in such waters. Reasonable restrictions on the times and methods of fishing should be prescribed after investigation, but the Bureau is without any authority or machinery to enforce regulations; and it is apparent that there should be some arrangement for cooperation between the Reclamation Service, which controls the reservoirs, and this Bureau, which will keep them supplied with fish.

Closely connected with this matter is the necessity for protecting the fish life in the irrigation canals and ditches in the West. The absence of guards or screens at the heads of ditches permits the fish to run in from the canals and become stranded. Furthermore, the annual draining of the canals and ditches leaves fish without water. In this way tremendous destruction of fish is now going on, and much larger loss will ensue later. It is therefore very important that general regulations be framed for the preservation of fish in such waters by requiring the use of effective screens or wheels.

INTERNATIONAL FISHERY MATTERS.

The treaty between the United States and Great Britain signed April 11, 1908, provides for joint governmental control and administration of the fisheries of the contiguous waters of the United States and Canada. To carry out the terms of the treaty two international fisheries commissioners have been appointed—Dr. David S. Jordan on behalf of the United States and Hon. S. T. Bastedo on behalf of Canada. The commissioners are charged with the preparation of uniform and common international regulations for the protection and preservation of the food fishes of the boundary waters. The field investigations preliminary to the formulation of the necessary regulations were conducted by the commissioners in the summer of 1908, and at the request of the Department of State the three chiefs of division of the Bureau were detailed to assist in these inquiries, which covered all the international waters from Passamaquoddy Bay to Puget Sound. The report of the commissioners has been placed in the hands of the President of the United States and the Governor-General of Canada for promulgation.

At the request of the Department of State the Bureau, as in the three previous years, detailed a representative to proceed to Newfoundland and report on the operations of American fishing vessels on the coast of that colony under the modus vivendi, pending the settlement of the dispute as to the rights of our fishermen under the

treaty of 1818. This detail extended from September, 1908, to January, 1909, during a part of which period the revenue cutter *Gresham* was assigned to this work and served as the headquarters of the Bureau's representative. American vessels that now resort to the "treaty shore" of Newfoundland are engaged only in the herring fishery. In 1908–9 these vessels numbered 42, whose catch consisted of 32,741 barrels of salted herring, valued at $132,695, and 18,157 barrels of frozen herring, valued at $105,095. Two other vessels were lost while in this fishery. Canadian vessels, several of which were chartered by American firms, secured 2,737 barrels of salted herring, worth $11,773, and 6,505 barrels of frozen herring, worth $29,273. The season passed without any disturbance.

INTERNATIONAL FISHERY CONGRESS.

The Fourth International Fishery Congress convened in the city of Washington in September, 1908, in response to an invitation extended in 1905 by the Department of Commerce and Labor and the American Fisheries Society. The foreign delegates gathered at the Department of State on the morning of September 22 and were greeted by the Acting Secretary, Hon. A. A. Adee. The opening meeting was held at the hall of the National Geographic Society, the United States Commissioner of Fisheries presiding. Addresses of welcome were made by Hon. Oscar S. Straus, Secretary of Commerce and Labor, on behalf of the United States; by Hon. Henry L. West, Commissioner of the District of Columbia, on behalf of the city of Washington; and by Dr. Hugh M. Smith, president of the American Fisheries Society, on behalf of the society. A response in the name of the foreign delegates was made by Dr. P. P. C. Hoek, scientific fishery adviser of the Dutch Government. The nominations of Prof. Hermon C. Bumpus, director of the American Museum of Natural History, as president of the congress, and of Dr. Hugh M. Smith, Deputy Commissioner of Fisheries, as secretary-general, were ratified, and fifteen vice-presidents from different countries represented were elected. Thereafter two sessions were held daily, the final meeting being on the afternoon of the 25th.

The membership of the congress numbered more than 400. Fifteen countries were represented by official delegates, and 11 other countries by delegates of societies and by private individuals. In addition to a number of delegates at large on behalf of the United States Government, four executive departments, the United States National Museum, and the Smithsonian Institution were officially represented. There were also duly appointed delegates from 43 American States and Territories and 20 American societies, clubs, and institutions. There were in attendance many of the leading fishery

workers of the world, and as a whole the gathering was the most noteworthy and important of the kind ever held in the Western Hemisphere.

There were presented a large number of papers of exceptional merit, which, with the discussion elicited, covered nearly every phase of fishing, fishery legislation, aquiculture, acclimatization, and scientific investigation of aquatic problems. Many of the papers were submitted in competition for the 18 cash prizes aggregating $2,200 offered by various institutions and individuals. By direction of the Secretary, the publication of the papers and proceedings of the congress will be undertaken by the Bureau, which has reserved for this purpose the Bulletin for 1908.

Among the resolutions and views adopted by the congress were the following: (1) Expressing pleasure that the long-standing fishery dispute between the United States and Great Britain affecting waters on the northeast coast of North America is to be submitted to settlement by arbitration; (2) commending the President of the United States for his stand in behalf of the conservation of natural resources; (3) advocating the establishment, in all countries having important fisheries, of national schools of fisheries and fish culture under government auspices; (4) urging the necessity of simplifying fishery laws by the elimination of qualifying clauses which often provide loopholes through which offenders may escape penalties and waters remain unprotected; (5) favoring the formation of the Appalachian Forest Reserve and other similar reserves which embrace the headwaters of important fishing streams; (6) advocating uniform measures on the part of the United States and Canada for the extermination or utilization of the dogfishes, in view of the great injury done thereby to the fishing industry; (7) reaffirming the action of former international fishery congresses in recommending an international oceanographic exploration of the Mediterranean in the interests of the fisheries.

This series of congresses was organized and inaugurated at Paris in 1900, the intervening meetings having been held at St. Petersburg in 1902 and Vienna in 1905. The next congress will convene at Rome in 1911.

EXPOSITIONS.

The Bureau took part in two expositions during the year, one at Seattle, Wash., and the other at Quito, Ecuador.

In an act of Congress approved May 27, 1908, special provision was made for the Bureau's participation in the Alaska-Yukon-Pacific Exposition, which opened at Seattle June 1, 1909, for a period of five and a half months. Preparations were begun in September, 1908, and by the opening day the installation had been completed and

the exhibit was ready. The exhibit was designed primarily to illustrate the operations of the Bureau in the study of the commercial fisheries, the propagation of fish, and the investigation of scientific matters pertaining to fishing and fish culture. The amount of money available did not permit a comprehensive display, but the functions, purposes, and work of the Bureau were shown in outline by an aquarium and a carefully selected series of apparatus, specimens, charts, and models. The exhibit occupied a separate building in the rear of and connected with the main government building. The fisheries annex was particularly convenient, well adapted for its purposes, and of ample dimensions to accommodate all the available material. The building contained 9,250 square feet of floor space, of which 5,500 square feet was devoted to the aquarium. The latter was a special feature, and contained fishes and other aquatic creatures of both fresh and salt water. It comprised 30 tanks of several sizes and a central pool for large specimens. Local waters were drawn on largely for stocking the aquarium, but interesting collections were sent from the East and from the coast of California. An assortment of fishes of the Hawaiian Islands, provided by those in charge of the Hawaiian exhibit, proved very attractive.

Under an act of Congress providing for the participation by the United States in an exposition to be held at Quito in commemoration of Ecuador's one hundredth anniversary of independence, this Bureau was called on for such material as would represent its functions for installation in the United States building. The exposition continued for a period of three months, beginning August 9, 1909. Owing to the very small amount of money available, the exhibit was necessarily confined to pictures, publications, maps, and a descriptive pamphlet printed in Spanish. The Bureau was awarded a grand premium for its exhibit.

PUBLICATIONS AND LIBRARY.

There were received from the Government Printing Office during the year the bound edition of the Annual Report and Bulletin for 1907 and 13 documents issued in pamphlet form. Reprints of 6 documents, mostly relating to fish-cultural subjects, were required to meet current requests for such information.

There is an active and widespread demand for the publications of the Bureau, many of which contain practical instructions for persons engaging in fish culture, in commercial fishing, in the preservation of fishery products, and in other branches of the industry. During the year 23,000 documents have been forwarded in response to specific requests and 7,500 additional have been sent to libraries, societies, educational institutions, and specialists at home and abroad whose names are on the permanent mailing list.

The library of the Bureau is strictly technical, and is maintained for the use of the office staff, the laboratories and stations, and outside collaborators. The accessions in 1909 numbered about 450. By exchange, the library receives all the fishery publications of foreign governments and societies, as well as those of the States and local organizations.

APPROPRIATIONS.

The resources of the Bureau for the fiscal year 1909 were $840,100, including a number of special appropriations; of this amount there was turned back into the Treasury from the annual appropriations an unexpended balance of $23,302.35. In accordance with law, the detailed expenditures under the different items will be reported to Congress. The appropriations were as follows:

Salaries:	
General	$305,820.00
Agents at Alaska salmon fisheries	4,500.00
Agents at seal fisheries	11,430.00
Miscellaneous expenses:	
Administration	8,000.00
Propagation of food fishes	275,000.00
Inquiry respecting food fishes	30,000.00
Statistical inquiry	7,500.00
Maintenance of vessels	70,000.00
Supplies for native inhabitants of Alaska on the seal islands	19,500.00
Specials:	
Repairs for steamer *Albatross*	18,000.00
Purchase of steam vessel for Alaska salmon inspection service	20,000.00
Establishment of a biological station in the Mississippi Valley	25,000.00
Construction and repair of buildings and other improvements for stations at—	
Baird, Cal	850.00
Duluth, Minn	9,000.00
Leadville, Colo	7,500.00
Construction and repair of buildings and other improvements, and purchase of land for stations at—	
Mammoth Spring, Ark	12,000.00
Erwin, Tenn	9,000.00
Cape Vincent, N. Y	7,000.00

RECOMMENDATIONS.

SALARIES.

In the estimate for appropriations required for the conduct of the work of the Bureau for the fiscal year beginning July 1, 1910, provision is made for the elimination of 5 low-grade clerkships and the substitution therefor of one senior clerk at $2,100 per annum, one at $1,980 per annum, and one at $1,800, thus leaving $900 per

annum as the minimum clerical pay. This will afford an opportunity to advance competent and deserving employees to grades in which they will receive salaries commensurate with the duties required and performed. It is further provided that the salaries of assistants in charge of divisions, chief clerk, superintendent of car and messenger service, two scientific assistants, and firemen and messengers be raised. These increases are in line with those proposed in the report of the Committee on Grades and Salaries transmitted to Congress by the President on February 11, 1908, and aggregate $9,820; and it is earnestly hoped that they will be granted, as thereby the efficiency of the service will be greatly enhanced. It is recommended also that the salaries of all seamen be advanced from $540 to $600 per annum; the pay of these employees is regarded as most inadequate, particularly as they are obliged to meet mess bills out of their salaries, thus leaving such a small balance that good, reliable men are not attracted to the service. The foregoing increases are more than offset by reductions in the estimates for construction work and miscellaneous expenses, so that the aggregate appropriations asked for 1911 are $32,640 less than were received for 1910.

In connection with this request for increases in salaries, the Commissioner desires to express his appreciation of the efficient and faithful service performed by officials and employees. The progress that has been made and the high standard that has been maintained in all branches of the work are directly due to the intelligent and zealous efforts of the Bureau's staff at headquarters and in the field.

EXTENSION OF FISH-CULTURAL WORK.

Notwithstanding the present magnitude of the fish-cultural operations of the Bureau, there is necessity for a substantial increase, in order that certain important sections may participate more thoroughly in the beneficial work of the federal fishery service and in order that the yearly augmented demands for food and game fishes may be met. The recomendations under this head in the last report are therefore renewed. There should be provided additional hatcheries in the Mississippi Valley and there should be a marked extension of the work of saving fishes from the overflowed lands in the same region. Recent experience has shown that in the southeastern part of Missouri the conditions are favorable for the establishment of a combination station for cultivation of pond fishes and for the rescue of fishes from the bayous and ponds that become dry each year. The previous recommendation for a fish-cultural experiment station is likewise resubmitted.

NEW OFFICE BUILDING.

The recommendation for a new building for the accommodation of the Bureau's offices in Washington is urgently renewed and emphasized. The present obsolete, unsuitable, cramped, unsafe, and unsightly quarters interfere with efficient administration and retard progress along important lines. Besides office quarters, there are required laboratory facilities, proper storage for collections, and a modern public aquarium which, while serving a most useful purpose in connection with the experimental work of the Bureau, would be one of the chief educational attractions of Washington.

Respectfully,

GEO. M. BOWERS,
Commissioner.

To Hon. CHARLES NAGEL,
Secretary of Commerce and Labor.

THE DISTRIBUTION OF FISH AND FISH EGGS DURING THE FISCAL YEAR 1909.

CHARACTER OF THE WORK.

More than 95 per cent of the output of the fish-cultural stations consists of important commercial species, notably the salmons, shad, whitefish, pike perch, yellow perch, white perch, lake trout, cod, pollock, flatfish, and lobsters. These are hatched in lots of many millions annually and planted by the Bureau, the fresh-water species principally in the large coastal streams and in the Great Lakes, the marine species upon the inshore fishing grounds of the Atlantic.

The cultivation of the fishes of the interior waters generally classed as game fishes, although a comparatively small factor in the total output, is a very important feature of the Bureau's work, supplying as it does various kinds of young fish for public streams, lakes and ponds, fishing preserves, private ponds, streams, etc., in all parts of the United States. Among the fishes most extensively cultivated for these purposes are the landlocked salmon, several species of trout, the grayling, the basses, crappie, bream, and catfish; various others also are handled. The trouts are artificially hatched from eggs taken from both wild and domesticated stock; the basses, catfish, and others are derived from mature fish held in ponds for breeding purposes, or (except the small-mouth black bass) they are rescued from the overflows of the Mississippi and Illinois rivers. Collections from the latter sources include also pike and pickerel, which are not distributed to applicants but are returned immediately to the main streams.

METHOD OF DISTRIBUTION.

The first consideration in the Bureau's distribution of fishes is to make ample return to the waters from which eggs or fish have been collected. The remainder of the product is consigned to suitable public or private waters upon application indorsed by a United States Senator or Representative, the Bureau furnishing to persons interested an application blank for this purpose. The blank calls for a description of the waters to be stocked, and by this information

is determined the species of fish that is suitable and the number that may be allotted to the water area in question. Certain predaceous species, such as the basses, perches, and pickerel, are not furnished for waters inhabited by trout or other valuable fishes to which they would be destructive. Nor, of course, are species like trout and salmon furnished for waters already stocked with fish that would prey upon them.

The fish are carried to their destination in railroad cars equipped for the purpose, or by messengers who accompany the shipments in baggage cars, and are delivered to the applicant free of charge, at the railroad station nearest the point of deposit. The applicant is advised by telegraph when the shipment will arrive, and is expected to make due provision for care of the fish until planted. Definite instructions in this respect are furnished at the time of shipment.

During the past fiscal year (July 1, 1908, to June 30, 1909) the Bureau received 10,112 applications for fish, nearly all for the game species. The demand, especially for the basses, crappie, and the catfish, has for some time been greater than could be met with available resources. The number of applications this year was 1,828 more than in 1908.

SIZE OF FISH WHEN DISTRIBUTED.

Fishes are distributed at various stages of development, according to the species, the numbers in the hatcheries, and the facilities for rearing. The commercial fishes—such as the shad, whitefish, lake trout, pike, perch, cod, etc., hatched in lots of many millions—are necessarily planted as fry shortly after hatching. Atlantic salmon, landlocked salmon, and various species of trout are reared, in such numbers as the hatchery facilities permit, to fingerlings from 1 to 6 inches in length; the remainder are distributed as fry.[a]

The basses, bream, and other sunfishes are distributed from some three weeks after they are hatched until they are several months of age. When the last lots are shipped the basses usually range from 4 to 6 inches and the sunfishes from 2 to 4 inches in length. The numerous fishes collected in overflowed lands—basses, crappie, sun-

[a] The varying usage in the classification of young fish as to size has caused such confusion and difficulty that the Bureau has adopted uniform definitions, as follows:

Fry=fish up to the time the yolk sac is absorbed and feeding begins.

Advanced fry=fish from the end of the fry period until they have reached a length of 1 inch.

Fingerlings=fish between the length of 1 inch and the yearling stage, the various sizes to be designated as follows: No. 1, a fish 1 inch in length and up to 2 inches; no. 2, a fish 2 inches in length and up to 3 inches; no. 3, a fish 3 inches in length and up to 4 inches, etc.

Yearlings=fish that are 1 year old, but less than 2 years old from the date of hatching; these may be designated no. 1, no. 2, no. 3, etc., after the plan prescribed for fingerlings.

fishes, catfishes, yellow perch, and others—are 2 to 6 inches in length when taken and distributed.

Eggs are distributed only to state hatcheries and, occasionally, to applicants who have hatchery facilities.

SIZE OF ALLOTMENTS.

The Bureau does not attempt to furnish to any one applicant more than a brood stock of fish for a given private pond or stream, it being expected that these will be protected until they have had time to reproduce. The number of fish in an allotment is, however, a variable quantity, depending upon the species and the age at which distributed. Brook trout, which are distributed both as fry and fingerlings, are allotted in much larger numbers as fry than as fingerlings 3 or 4 inches long. Pike perch, which, owing to there excessive cannibalism, can not be reared and are consequently distributed as fry, may be supplied in lots of half a million, where an equal water area would receive only 200 or 300 young bass from 2 to 5 inches long. These latter larger fish have a much better chance of reaching maturity than have the fry, and the actual value for stocking purposes of a few hundred fingerling bass may therefore equal many thousand times this number of pike perch fry.

SPECIES CULTIVATED IN 1909.

The species cultivated by the Bureau in 1909 numbered some 50 fishes and the lobster. Of these the following were artificially propagated:

THE CATFISHES (SILURIDÆ):
- Horned pout, bullhead, yellow cat (*Ameiurus nebulosus*).
- Marbled cat (*Ameiurus nebulosus marmoratus*).

THE SHADS AND HERRINGS (CLUPEIDÆ):
- Shad (*Alosa sapidissima*).

THE SALMONS, TROUTS, WHITEFISHES, ETC. (SALMONIDÆ):
- Common whitefish (*Coregonus albus* and *C. clupeaformis*).
- Lake herring, cisco (*Argyrosomus artedi*).
- Chinook salmon, king salmon, quinnat salmon (*Oncorhynchus tschawytsha*).
- Silver salmon, coho (*Oncorhynchus kisutch*).
- Blueback salmon, redfish, sockeye (*Oncorhynchus nerka*).
- Humpback salmon (*Oncorhynchus gorbuscha*).
- Steelhead trout, hardhead (*Salmo gairdneri*).
- Rainbow trout (*Salmo irideus*).
- Atlantic salmon (*Salmo salar*).
- Landlocked salmon (*Salmo sebago*).
- Yellowstone Lake trout, cutthroat trout, blackspotted trout (*Salmo lewisi*).
- Golden trout (*Salmo roosevelti*). Distribution not yet undertaken.
- Sea trout (*Salmo trutta*). Introduced species.
- Loch Leven trout (*Salmo trutta levenensis*). Introduced species, propagated in limited numbers for observation under natural conditions.
- Lake trout, Mackinaw trout, longe, togue (*Cristivomer namaycush*).
- Brook trout, speckled trout (*Salvelinus fontinalis*).
- Sunapee trout (*Salvelinus aureolus*).

THE GRAYLINGS (THYMALLIDÆ)

Montana grayling (*Thymallus montanus*).

THE BASSES, SUNFISHES, AND CRAPPIES (CENTRARCHIDÆ):

Crappie (*Pomoxis annularis*).
Strawberry bass, calico bass (*Pomoxis sparoides*).
Rock bass, red-eye, goggle-eye (*Ambloplites rupestris*).
Warmouth, goggle-eye (*Chænobryttus gulosus*).
Small-mouth black bass (*Micropterus dolomieu*).
Large-mouth black bass (*Micropterus salmoides*).
Bream, bluegill sunfish (*Lepomis pallidus*).
Other sunfishes, chiefly *Eupomotis gibbosus*.

THE PERCHES (PERCIDÆ):

Pike perch, wall-eyed pike, yellow pike, blue pike (*Stizostedion vitreum*).
Yellow perch, ring perch (*Perca flavescens*).

THE SEA BASSES (SERRANIDÆ):

Striped bass, rockfish (*Roccus lineatus*).
White bass (*Roccus chrysops*).
White perch (*Morone americana*).
Yellow bass (*Morone interrupta*).

THE SMELTS (ARGENTINIDÆ):

American smelt (*Osmerus mordax*).

THE CODS (GADIDÆ):

Cod (*Gadus callarias*).
Pollock (*Pollachius virens*).

THE FLOUNDERS (PLEURONECTIDÆ):

Winter flounder, American flatfish (*Pseudopleuronectes americanus*).

CRUSTACEANS:

American lobster (*Homarus americanus*).

After the annual seasons of high water in the Mississippi basin, great numbers of young fish are left in sloughs and pools when the waters have receded, and would eventually die by the drying up of these shallow places in summer or freezing in winter. Large collections are made from such sources, for return to the original streams and, of the most abundant species, also to supplement the hatchery stock for distribution. The fishes so collected in 1909 were as follows:

THE CATFISHES (SILURIDÆ)

Spotted cat, blue cat, channel cat (*Ictalurus punctatus*). Only limited numbers obtainable.
Horned pout, bullhead, yellow cat (*Ameiurus nebulosus*).

THE SUCKERS AND BUFFALOFISHES (CATOSTOMIDÆ):

Small-mouth buffalofish (*Ictiobus bubalus*).

THE MINNOWS AND CARPS (CYPRINIDÆ):

Carp (*Cyprinus carpio*). Distributed in rare instances, for waters unsuited to other species.

THE PIKES AND PICKEREL (ESOCIDÆ):

Pike (*Esox lucius*). Restored to the streams; not distributed.

Pickerel (*Esox reticulatus*). Restored to the streams; not distributed.

THE BASSES, SUNFISHES, AND CRAPPIES (CENTRARCHIDÆ):

Crappie (*Pomoxis annularis*).

Rock bass, red-eye, goggle-eye (*Ambloplites rupestris*).

Warmouth, goggle-eye (*Chænobryttus gulosus*).

Large-mouth black bass (*Micropterus salmoides*).

Bream, bluegill sunfish (*Lepomis pallidus*).

Other sunfishes (chiefly *Eupomotis gibbosus*).

THE PERCHES (PERCIDÆ):

Yellow perch, ring perch (*Perca flavescens*).

THE CROAKERS (SCIÆNIDÆ):

Fresh-water drum, sheepshead, gaspergou (*Aplodinotus grunniens*). Only limited numbers obtainable. Not distributed.

Certain introduced species are propagated to a limited extent, as follows:

THE MINNOWS AND CARPS (CYPRINIDÆ):

Goldfish (*Carassius auratus*). Propagated for ornamental purposes; not distributed.

Tench (*Tinca tinca*). Cultivated varieties, green tench and golden tench. Propagated for ornamental purposes; not distributed.

Ide (*Leuciscus idus*). Cultivated variety, golden ide. Propagated for ornamental purposes; not distributed.

OUTPUT.

SUMMARIZED STATEMENT.

The fish-cultural work of the Bureau during the fiscal year 1909 attained its highest record, with an output of 3,107,131,911. Of this number 2,382,573,208 were young fish, distributed for the stocking and replenishing of public and private waters, and the remaining 724,558,703 were eggs, delivered to state and foreign hatcheries. The output of young fish exceeds the greatest previous record for any one year by over 611,000,000.

Flatfish, pike perch, blueback salmon, white perch, lake, black-spotted, and steelhead trouts, landlocked salmon, bream, crappie, small-mouth bass, and rock bass show the largest increases over last year. The number of yellow perch, shad, Atlantic salmon, and rainbow trout was smaller than in the preceding year, but the decrease was a normal one.

SUMMARY OF DISTRIBUTION OF FISH AND EGGS, FISCAL YEAR ENDED JUNE 30, 1909.

Species.	Eggs.	Fry.	Fingerlings, yearlings, and adults.	Total.
Catfish			562,580	562,580
Carp			7,807	7,807
Buffalofish			57,400	57,400
Shad	266,000	57,112,000		57,378,000
Whitefish	142,220,000	277,445,000		419,665,000
Chinook salmon	38,859,265	20,177,286	75,429	59,111,980
Silver salmon	272,000	9,470,925		9,742,925
Blueback salmon	100,000	93,409,496		93,509,496
Humpback salmon		10,000	100	10,100
Steelhead trout	271,468	2,181,413	46,500	2,499,381
Rainbow trout	286,150	292,408	2,026,463	2,605,021
Atlantic salmon		647,790	24,435	672,225
Landlocked salmon	570,000	793,550	237,896	1,601,446
Blackspotted trout	602,820	5,993,943	2,049,395	8,646,158
Loch Leven trout			70,000	70,000
Lake trout	22,806,000	27,188,177	1,345,100	51,339,277
Brook trout	905,000	5,821,322	3,723,489	10,449,811
Sunapee trout		229,736		229,736
Scotch sea trout			47	47
Grayling	350,000	808,000	6,032	1,164,032
Pike			44,200	44,200
Crappie and strawberry bass		62,500	217,355	279,855
Rock bass			51,112	51,112
Warmouth bass			2,278	2,278
Small-mouth black bass		262,674	111,924	374,598
Large-mouth black bass		32,500	540,962	573,462
Sunfish			317,888	317,888
Pike perch	457,850,000	187,050,000		644,900,000
Yellow perch	10,000,000	213,610,410	50,873	223,661,283
Striped bass		4,518,000		4,518,000
White perch	24,500,000	318,760,000	2,650	343,262,650
Yellow bass		136,938	1,225	138,163
Smelt	24,700,000	9,400,000		34,100,000
Freshwater drum			25,000	25,000
Cod		153,536,000		153,536,000
Flatfish		786,626,000		786,626,000
Pollock		30,890,000		30,890,000
Lobster		164,509,000		164,509,000
Total	724,558,703	2,370,975,068	11,598,140	3,107,131,911

WORK AND OUTPUT OF THE STATIONS.

The following tabulation lists all of the stations operated by the Bureau in 1909, and shows for each the period of operation, the kinds of fishes handled, and the number of fish and eggs produced. It shows also the character of the work in each locality and in some degree the relative importance of the stations, the latter statement being qualified for particular instances. Some substations are more important in the actual fish-cultural work than are the stations to which they are, for purposes of administration, subordinate; but the output of these important substations is not always shown separate from that of the main hatchery. Distinctions are indicated to some extent in the table by means of a scheme of type: All of the stations and all of the substations where eggs were hatched are printed in ordinary roman type, with marginal indentions to show their relative administrative status; substations which were merely collecting points, perhaps shifting in location from year to year, are printed in italics, and their output is ordinarily included with the output of that species credited to the main station. The transfers of eggs and fish from station to station are recorded in foot-

notes under the station from which taken, and the yield is credited to the receiving station. Transfers of eggs are frequent, serving convenience and economy in transportation to stations which are to be distributing centers for the respective species, since the shipment of eggs is easier and cheaper than the shipment of young fish.

STATIONS OPERATED AND THE OUTPUT OF EACH.

Station.	Period of operation.	Species handled.	Eggs.	Fry.	Fingerlings, yearlings, and adults.
Afognak, Alaska	Entire year	Blueback salmon		39,325,870	
		Humpback salmon		10,000	
Baird, Cal.[a]	do	Chinook salmon	5,078,065	3,590,078

[a] For convenience in handling, the following transfers were made:
St. Johnsbury to other stations, 15,000 brook trout eggs, 250,000 brook trout fry, 5,000 landlocked salmon fry, and 5,000 lake trout fry.
Arlington to St. Johnsbury, 15,000 brook trout fingerlings.
Swanton to St. Johnsbury, 1,700,000 yellow perch eggs.
Spearfish to other stations, 1,400,000 blackspotted trout eggs and 5,000 rainbow trout fingerlings.
White Sulphur Springs to Wytheville, 8,000 brook trout fingerlings.

STATIONS OPERATED AND THE OUTPUT OF EACH—Continued.

Station.	Period of operation.	Species handled.	Eggs.	Fry.	Fingerlings, yearlings, and adults.
Wytheville, Va.[a]	Entire year	Rainbow trout	220,000		434,965
		Brook trout			214,700
		Carp			105
		Pike perch		500,000	
		Large-mouth black bass.		6,500	7,084
		Rock bass			21,585
		Bream			175
		Small-mouth black bass.		6,500	120
Yes Bay, Alaska	do	Blueback salmon		48,053,000	
		Silver salmon		9,000	

[a] For convenience in handling, there were transferred from Wytheville to other stations 562,000 rainbow trout eggs, 30 carp, 8,000 rainbow trout fingerlings, and 19,550 rock bass fingerlings.

ALLOTMENTS TO STATE FISH COMMISSIONS.

As usual, various state fish commissions were supplied from the Bureau's stock with eggs to be hatched and distributed under their respective auspices. Following is a record of such allotments in 1909:

ALLOTMENTS OF FISH EGGS TO STATE FISH COMMISSIONS, FISCAL YEAR ENDED JUNE 30, 1909.[a]

State and species.	Eggs.	State and species.	Eggs.
California:		New York—Continued.	
Chinook salmon	32,039,265	Landlocked salmon	30,000
Connecticut:		Rainbow trout	20,000
Lake trout	300,000	Blackspotted trout	25,000
Brook trout	30,000	Ohio:	
White perch	5,000,000	Pike perch	158,725,000
Yellow perch	10,000,000	Whitefish	55,548,000
Illinois:		Oregon:	
Rainbow trout	50,000	Chinook salmon	6,581,000
Whitefish	7,000,000	Brook trout	310,000
Pike perch	25,000,000	Blackspotted trout	100,000
Maine:		Steelhead trout	50,000
Landlocked salmon	300,000	Pennsylvania:	
Brook trout	300,000	Pike perch	223,125,000
Maryland:		Lake trout	3,000
Rainbow trout	50,000	Blackspotted trout	25,000
White perch	2,000,000	Silver salmon	75,000
Massachusetts:		Whitefish	58,572,000
Rainbow trout	50,000	Vermont:	
Michigan:		Lake trout	400,000
Landlocked salmon	30,000	Washington:	
Lake trout	3,500,000	Steelhead trout	50,000
Pike perch	50,000,000	Wisconsin:	
Smelt	22,500,000	Lake trout	12,126,000
Nevada:		Whitefish	20,000,000
Steelhead trout	50,000	Wyoming:	
New Hampshire:		Grayling	350,000
Silver salmon	50,000	Brook trout	50,000
Landlocked salmon	50,000	Blackspotted trout	210,000
Lake trout	300,000	Landlocked salmon	10,000
New York:		Steelhead trout	60,000
White perch	12,350,000		
Lake trout	3,000,000		

[a] Also there were allotted to California 765 crappie and strawberry bass, 3,600 bream, and 240 yellow perch fingerlings, yearlings, and adults; to Colorado, 50,000 blackspotted trout fry; to Minnesota, 4,420 crappie and strawberry bass and 816 large-mouth black bass fingerlings, yearlings, and adults; and to New York, 200,000 brook trout fry.

In the collection of whitefish and pike perch eggs on Lake Erie the Bureau had the active cooperation of the Ohio and Pennsylvania fish commissions.

SHIPMENTS TO FOREIGN COUNTRIES.

In response to requests reaching the Bureau through the Department of State, fish ova to the number of 568,150 have been doated to foreign countries, as follows:

SHIPMENTS TO FOREIGN COUNTRIES DURING THE FISCAL YEAR 1909.

Country and species.	Number.	Country and species.	Number.
Argentina:		France:	
Blueback salmon	100,000	Brook trout	10,000
Brook trout	50,000	Lake trout	10,000
Chinook salmon	200,000	Germany:	
Lake trout	50,000	Rainbow trout	16,150
Landlocked salmon	15,000		
Rainbow trout	25,000	Total	568,150
Silver salmon	92,000		

Through the courtesy of the Canadian fishery authorities the Bureau, as heretofore, has maintained at Rossport, Ontario, as an adjunct of the Duluth (Minnesota) hatchery, a station for the collection of eggs of the lake trout.

CONDITION AND EXTENT OF THE OYSTER BEDS OF JAMES RIVER, VIRGINIA

By H. F. Moore

Assistant, U. S. Bureau of Fisheries

Bureau of Fisheries Document No. 729

PREFACE.

On February 3, 1909, the Bureau of Fisheries received from Hon. Claude A. Swanson, governor of Virginia, a communication inclosing the following resolution of the Commissioners of Fisheries of the State:

Resolved, That the governor be requested to enlist the services of the United States Bureau of Fisheries in determining and defining the fertile and the barren areas in James River, marking and platting same, provided it can be done without expenditure by the State.

At the urgent solicitation of Governor Swanson, and upon the conviction that the work would prove of value as a guide for contemplated legislation by the State in respect to the future administration of the public oyster grounds, the request for the survey was acceded to, the steamer *Fish Hawk* and civilian assistants were detailed for the work, and Dr. H. F. Moore, assistant in the Bureau of Fisheries, was directed to assume charge.

The erection of signals was begun early in July and completed by August 7. The actual examination of the oyster beds commenced on August 9 and extended, with only such interruptions as were due to the weather, to September 14, the survey thus covering the period just prior to the opening of the oyster season, when the beds were in their optimum condition. Under the terms of the resolution quoted above, the Bureau has not felt justified in offering advice as to the future treatment of the beds, and the following report is therefore confined to statements of fact and a short discussion of their several obvious avenues of application.

GEORGE M. BOWERS,
Commissioner.

UNITED STATES BUREAU OF FISHERIES,
Washington, D. C., December 1, 1909.

CONDITION AND EXTENT OF THE OYSTER BEDS OF JAMES RIVER, VIRGINIA.

By H. F. Moore,
Assistant, U. S. Bureau of Fisheries.

PREVIOUS SURVEYS.

Prior to the investigations made by the Bureau of Fisheries in July, August, and September, 1909, two surveys of the James River oyster beds had been made, neither of which professed to delineate the rocks accurately or to furnish detailed information concerning their productiveness and condition. The first of these surveys was a reconnoissance made in 1878 by Lieut. (then Master) Francis Winslow, U. S. Navy, in command of the Coast and Geodetic Survey schooner *Palinurus*. The second was the survey of the public grounds by Mr. J. B. Baylor, assistant, Coast and Geodetic Survey, under the authority of the State, in 1892 and preceding years.

As Winslow himself states, his "examination of these beds was a very hurried one, and the delineation must be regarded as merely approximate, being the result of a hasty reconnoissance." The chart published with the report delineates merely the general outlines of the oyster-bearing areas, without attempting to show the smaller individual rocks or the density of growth, and the text is of very general character. Comparing the chart with the results of the recent survey, however, it is evident that Lieutenant Winslow's brief investigation must have shown with considerable accuracy the general distribution of oysters in the James and Nansemond rivers at that time. The differences between the general results of the two surveys are such as could be readily produced by the lapse of time and the vicissitudes through which the beds have passed under the operation of natural and human agencies. Some areas have become depleted through the intensive fishing they have sustained, or from the effects of freshets and other physical factors, while on the other hand some appear to have had their boundaries extended or have become merged with adjacent beds through the operations of the tongers.

The Baylor survey was of an entirely different character from that conducted by Winslow. It was in no sense an examination of the oyster beds themselves, but primarily and avowedly a delimitation of boundaries which included the recognized or reputed oyster-bearing bottom, as pointed out by local commissioners or representatives of each oyster-producing county. It is the writer's understanding that the county commissioners were, under the state law ordering the survey, the final arbiters with whom rested the decision whether or not a given area should be included within the boundaries of the public grounds. So far as can be learned no examinations whatever were made on the beds, the commissioners using their judgment and local knowledge in selecting the corners and the engineers with their theodolites cutting in the points indicated from stations on the shore.

Whether or not beds were omitted from the confines of the public grounds so located can not now be satisfactorily determined, owing to the development of the planting industry, outside of the Baylor lines, on all or most of the available bottom. It is evident, however, that in the region under discussion no very extensive rocks were disregarded, and a comparison of the results of the recent survey with that of 1892 shows that the Baylor lines, considered as a broad scheme of delimitation, conform closely with the general distribution of the rocks. At several places, notably on Gun and Kettle Hole rocks, parts of the natural beds undoubtedly fell outside of the lines, but the writer hazards the suggestion that this may not have been through inadvertence but because those parts of the rocks may have been already taken up as private holdings.

It has been claimed, and Mr. Baylor himself has so stated in official communications to the State, that a very considerable area of barren bottom, amounting to many thousand acres, was included within the public grounds. That this should be so, under the system adopted by the local commissioners and under the desire to assure the inclusion of all naturally productive bottom, was inevitable. Moreover, the boundaries of the beds are irregular curves, while the including surveyed boundaries must be straight lines, for purposes of administration and policing as long and unbroken as possible. To have excluded the greater part of this barren bottom would have necessitated a careful location of the natural rocks and the breaking up of the public grounds into a considerable number of small or moderate areas instead of segregating them into a few large ones.

To what extent the claim that great areas of barren bottom are included in the public grounds is justified will appear from the accompanying charts and in the following descriptions and discussions.

METHODS OF THE PRESENT SURVEY.

To furnish authoritative and definite information as to the actual extent and condition of the natural rocks and the character of the bottoms embraced within the boundaries of the public beds, it was necessary to depart widely from the methods of the previous surveys.

It was decided to confine the investigation wholly to the public beds, passing their boundaries only far enough to give assurance that the entire area had been covered. Nothing was to be gained by an examination of the excluded areas, as it is now almost impossible to determine whether natural rocks were omitted from the grounds laid out in 1892, and it is too late to correct such omissions if they could be determined. For legal purposes, all that is not avowedly public ground is barren bottom, and if held under leasehold from the State can not be alienated from the possession of the lessees as long as the law has been complied with.

The methods followed have been essentially those pursued in former surveys conducted by the Bureau of Fisheries, with the changes and improvements dictated by recent experience and the local conditions.

The Coast and Geodetic Survey furnished projections on which were platted the triangulation points used in former surveys by that bureau. Several of these points, including the light-houses, were "recovered," and from them the signals, usually tripods, erected where necessary, were cut in and platted by means of the sextant and 3-arm protractor. This method, while lacking the great precision attained by means of the best theodolites and the nice computations employed by the Coast Survey in its work, insures an accuracy more than sufficient for the purposes of an oyster survey.

The oyster beds were discovered by soundings with a lead line, but principally by means of a length of chain dragged over the bottom at the end of a copper wire running from the sounding boat. The wire was wound on a reel, and its unwound length was adjusted to the depth of water and the speed of the launch, so that the chain was always on the bottom. Whenever the chain touched a shell or an oyster the shock or vibration was transmitted up the wire to the hand of a man whose sole duty it was to give heed to such signals and report them to the recorder.

The launches from which the soundings were made were run at a speed of between 3 and 4 miles per hour, usually on ranges ashore to insure the rectitude of the lines. At intervals of three minutes—in some cases two minutes—the position of the boat was determined by two simultaneous sextant observations of the angles between a set of three signals, the middle one of which was common to the two angles, the position being immediately platted on the boat sheet. At regular intervals of twenty seconds, as measured by

a clock under the observation of the recorder, the leadsman made a sounding and reported to the recorder the depth of water and the character of the bottom, immediately after which the man at the wire reported the character of the chain indications since the last sounding—that is, whether they showed barren bottom or dense, scattering, or very scattering growths of oysters.

With the boat running at 3 miles an hour the soundings were between 80 and 90 feet apart and, as the speed of the boat was uniform, the location of each was determinable within a yard or two by dividing the platted distance between the positions determined by the sextant by the number of soundings. The chain, of course, gave a continuous indication of the character of the bottom, but the record was made at the regular twenty-second intervals observed in sounding.

The chain, while indicating the absence or the relative abundance of objects on the bottom, gives no information as to whether they are shells or oysters, nor, if the latter, their size and condition. To obtain this data it was necessary to supplement the observations already described by others more definite in respect to the desired particulars. Whenever in the opinion of the officer in charge of the sounding boat such information was required, a numbered buoy was dropped, the time and number being entered in the sounding book. Another launch, following the sounding boat, anchored alongside the buoy, and a quantity of the oysters and shells were tonged up, separated by sizes, and counted.

In former surveys made by the writer, in order to arrive at an estimate of the density of the oyster growth a definite area, usually 5 yards, was staked off by means of steel-shod pikes and everything was removed from the bottom and counted. This method is accurate, but slow and difficult in deep water, and, as it was desirable to make a large number of observations, the system developed in the Maryland survey was adopted. This consists essentially in making a known number of "grabs" with the oyster tongs, exercising care to clean the bottom of oysters as thoroughly as possible at each grab. In a given depth of water and using the same boat and tongs an oysterman will cover practically the same area of the bottom at each grab, but, other factors remaining the same, the area of the grab will decrease with an increase in the depth.

Careful measurements were made and tabulated showing the area per grab covered by the tonger employed on the work at each foot of depth of water and for each pair of tongs and boat used. With this data, and knowing the number of "grabs," the number of oysters of each size per square yard of bottom was readily obtainable by simple calculation. The following example will illustrate the data obtained and the form of the record:

DEPARTMENT OF COMMERCE AND LABOR.

BUREAU OF FISHERIES.

Field record of examinations of oyster beds.

General locality: *James River.*
Local name of oyster ground: *Between Rock wharf and Spindle rock.*
Date: *August 28, 1909.* Time: *9.25 a. m.*
Angle: *F. 140.* Buoy No.: *23.*
Depth: *7 feet.* Bottom: *Hard.*
Condition of water: *Medium clear.*
Density: ..... Temperature: .....
Current: ..... Stage of tide: .....
Tongman: *Lawrence, in flatboat.*
No. grabs made: *8.* Tongs: *14 feet.*
Total area covered: *3½ square yards*.....

No. oysters taken: −1 in.: *27.* 1 in. −X in.: *69.*
X in. −4 in.: *10.* 4 in.: *3.*

Quantity shells: *½ bushel.*

Result: Spat per square yard: *7.7.*
Culls per square yard: *19.7.*
Counts per square yard: *3.7.*

X in.=cull limit prescribed by law.

This furnishes an exact statement of the condition of the bed at a spot which can be platted on the chart with error in position of not more than a few yards. From the data obtained a close estimate may be formed of the bushels of oysters and shells per acre in the vicinity of the examination and, by multiplying the observations, for the bed as a whole. In the course of the survey 590 observations were made at various places, principally on the natural rocks, but some on the barren bottoms also.

In former surveys by the Bureau the relative density of the oyster growth has been considered solely from the standpoint of the total quantity of oysters. That method is satisfactory where the depth is fairly uniform throughout the region examined, but was not considered accurate enough for the purposes of the present report.

With a given quantity of oysters per square yard or acre, a bed lying in shoal water is more valuable commercially than one in deep water, owing to the fact that the labor of the tonger is more efficient in the former. As has been pointed out, the area covered by a "grab" decreases with an increase in depth, and, moreover, the deeper the water the greater is the labor involved in making the "grab" and the smaller is the number of grabs which can be made per hour or per day. With 14-foot tongs used from a canoe, such as is employed

on the James River, an oysterman can cover twice as much bottom per grab in 4 feet as he can in 8 feet, and about two and one-half times as much as he can using 20-foot tongs in 16 feet. Using the tongs stated, the average tonger observed in Maryland, and the data will hold in Virginia, will make about 2.7 grabs per minute in 4 feet, 2.6 in 8 feet, and 1.8 in 16 feet of water. In other words, if he can cover 1 square yard of the bottom in a given time in 16 feet, he can cover 1.7 yards in 8 feet, and 3.3 yards in 4 feet of water.

It is obvious that if a tonger in a given time is to obtain the same quantity of oysters in each of these depths, the oyster growth must lie on the bottom with a density inversely to the areas stated above. The value of a bed, the price per bushel of the oysters being the same, depends on the quantity which a man can take in a given time, and it therefore happens that a bed in deep water may be valueless commercially, while another rock, with the same density of growth but covered by shoaler water, may be tonged with profit.

Based on these principles, and taking into consideration the number of oysters per bushel on the different beds as determined by actual counts, tables were prepared showing the number of oysters per square yard for each foot of depth necessary to yield to the tonger 1 bushel of oysters per day of tonging. From these data the beds were divided into areas, according to the number of bushels of oysters which they were capable of yielding per day to the tonger, based on nine hours of actual tonging and disregarding the time occupied in culling. The bottom was divided into 5 categories: Barren, on which there were neither shells nor oysters; depleted, on which the tonger could take less than 3 bushels of market oysters or 4 bushels of seed, according to location; very scattering growth, on which between 3 and 5 bushels of oysters or 4 and 8 bushels of seed could be taken; scattering growth, on which the limits were 5 and 8 bushels of market oysters or 8 and 12 bushels of seed; and areas of dense growth, on which upward of 8 bushels of market oysters or 12 bushels of seed could be taken per day.

During the survey 10,440 soundings were taken, and the position of the boat was instrumentally determined at 1,369 places. The chain was dragged for 226 miles, giving continuous indications of the character of the bottom, which were plotted on the chart at 10,440 places. The density of oyster growth was determined by the 590 biological observations already referred to, and the extent and boundaries of the areas as charted were fixed by a combination of these observations and the 10,440 records of the continuous chain readings. During the work the writer was in charge of the sounding boat and in constant touch with all operations. The biological observations were all under the immediate charge of Mr. T. E. B. Pope, whose

experience in such work is such as insured their accuracy both as to the area covered by the tonger and the quantity of oysters taken. The oysters brought in by the biological party were all examined by the author, who has also personally made all of the many calculations required and directly supervised the laying off of the areas on the charts. The basis for the determination of the character of the beds was decided on in advance, but the work of the survey was so planned that it was impossible for any member of the party to form an opinion as to the conditions found until after the field work was completed, and any involuntary prejudice was thus eliminated as far as possible. The author himself could form but a vague idea of the general results until the charts were completed and the report almost written.

In the following pages the subject is gradually developed from a detailed description of the several parts of the individual natural rocks to a broad consideration of the market oyster and seed areas as a whole, and in every case there is given the principal data on which the several statements are based.

OYSTER ROCKS.

The term "oyster rock," as used in Virginia and employed in this report, is synonymous with natural oyster bed and is to be distinguished from the term "public ground," which is used to designate the areas legally embraced within surveyed lines and set apart for the use of the public. The public grounds were intended to embrace all of the oyster rocks, and usually each includes a number of the latter within its confines.

An oyster rock is usually a more or less definite area of bottom, limited by the extent of actual oyster growth. Originally, the boundaries were rather definitely marked and the rocks were separated from one another by barren areas, but the operations of oystering have in many cases strewn oysters and shells over the surrounding bottom, so that in cases the original limits have become obscured and adjacent rocks merged.

On the accompanying chart much of the bottom indicated as depleted really represents the areas which have been thus covered with scattered oysters and shells, and the term employed indicates that oysters and shells are very scarce rather than that they have been removed, though the latter is the fact in many cases. The so-called "depleted" areas are those on which oysters grow in quantities much below those which would make it commercially profitable to tong for them.

The boundaries of the rocks, as shown by the red inclosing lines on the charts and as considered in the text, were defined by the

results of the chain indications, the methods of obtaining which have been before explained. All areas in which shells or oysters were encountered are regarded as rocks, but their character, so far as productiveness is concerned, was determined by tonging and counting the yield in the manner heretofore described. The depleted areas, except where it is shown that they contain a reasonably heavy growth of young, may be regarded as worthless from the viewpoint of the tonger; the areas of very scattering growth are of doubtful value except where a heavy growth of young oysters indicates potential improvement, while the areas of scattering and dense growth can be regarded as really productive natural rocks. The barren bottom, which is shown on the chart as an unshaded area outside of the red lines, is that on which neither oysters nor shells were found. A few small unshaded areas inclosed by red lines indicate beds the exact nature of which was not accurately determined.

An attempt is made in this report to designate the rocks by the names employed by the oystermen, so far as these could be ascertained. In several cases, as for instance "Fishing Point Rocks" and "Marshy Island Rock," names have been coined to serve the purposes of reference and designation. The exact extent of Point of Shoals Rock was not definitely ascertained, and as shown on the chart it may not accord with the usage of the oystermen. There was also some doubt about the location of Kettle Hole and Thomas Point Rocks, but, as the names used in the text are clearly shown on the charts, there can be no confusion in the references. In a number of cases where the several beds were more or less continuous with one another arbitrary boundaries have been adopted, but, as these usually pass through depleted areas and as in a later discussion the rocks are considered as a whole in their grouping in the public beds, the necessity for this treatment causes no loss in the final accuracy or exactitude.

In the following pages the rocks are considered in detail.

MARKET OYSTER AREA.

HOLLANDS ROCK.

This was intended to be included by the Baylor survey in Public Ground No. 3, Nansemond County, though it is stated that a mistake was made by which it was omitted. The area, 22 acres, which is described under this name included the only bottom within the public ground which gave any indication of being an oyster bed, though the examination showed it to be depleted. It is completely surrounded by planted beds.

The results of the examination were as follows:

DETAILS OF EXAMINATION OF HOLLANDS ROCK.

Station number.	Date of examination.	Mean depth of water.	Character of growth of market oysters.	Oysters caught per square yard.			Estimated quantity of oysters per acre.

NANSEMOND RIDGE ROCK.

This is the principal and only productive bed in Nansemond River. It lies mainly on and about a shoal extending through the middle of the river from Cedar Point almost to the middle of James River, opposite Newport News. At its northern end it is connected, by an unproductive, practically barren area, with three smaller rocks hereafter described. Its area, density of oyster growth, and contents are as follows:

OYSTER GROWTH ON NANSEMOND RIDGE ROCK.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Dense	85	148	93	7,905
Scattering	446	133	60	26,760
Very scattering	294	34	37	10,878
Depleted	782	35	11	8,602
Total	1,607			54,145

The market oysters on this bed are large, averaging at the time of the survey a few over 300 per bushel. They are said to attain a good condition, particularly late in the season, and are used mainly by shucking houses. The small oysters ran about 750 per bushel.

The broadest, largest, and most productive part of the bed stretches northward from opposite Pig Point on the west side of the channel. It is estimated that this portion has an area of about 1,156 acres, of which 69 acres bear a dense growth of market oysters, 386 acres a scattering growth, 201 acres a very scattering growth, and 500 acres are depleted. The latter does not include the barren bottom embraced between the edges of the bed and the lines of the Baylor survey. It is further estimated that on the dense bottom a man tonging exclusively could take in a day about 10 bushels of market oysters, on the scattering area about 6 bushels, on the very scattering part about 3½ bushels, while on the depleted area he could not take an average of over 1 bushel. These estimates are for the beginning of the season,

and any considerable tonging of the beds would soon materially reduce the average catch per day.

In the dense and scattering parts of this portion of the bed, especially near the crest of the ridge, there is a growth of small oysters so dense that an average of upward of 12 bushels could be tonged per day, and these areas can undoubtedly be regarded as both presently and prospectively productive. There is also a dense growth of young oysters on the inner parts of the depleted area opposite Nansemond River Light. On the areas of very scattering growth the small oysters are in even smaller quantity than the market oysters, but in places there are clean shells in sufficient quantity to indicate that under proper conditions a good set might occur and the bottom become fairly productive.

Above a line drawn between Pig Point and Barrel Point the bed may be divided into two parts, one a tail-like continuation of the main bed running along the eastern edge of the channel and the other a detached portion lying on a shoal west of the channel, north of Larkins Rock. The former has 126 acres of depleted bottom and two small patches, one of scattering growth covering about 22 acres and the other of about 41 acres on which the oysters are very scattering. The detached area covers about 260 acres, of which 15 are dense, 39 scattering, 51 very scattering, and 155 depleted. On the areas of dense and scattering growths of market oysters there is a heavy growth of culls, but the scattering and depleted areas are generally impoverished of young.

On the two areas just described as lying above a line between Pig and Barrel points it is estimated that there are 15 acres of dense growth on which a man could tong an average of about 8 barrels of market oysters per day, 61 acres on which he could average about 5 bushels, 92 acres of very scattering growth where he could take about 4 bushels per day, and 281 acres of depleted bottom which will not yield 1 bushel per day. On the depleted area there are few young oysters and practically no shells. The barren bottom lying within this part of the Baylor survey, on which oysters do not now grow and apparently never have grown in marketable quantities, nearly equals all of the foregoing combined, covering about 430 acres. The barren and depleted bottom together aggregate about 711 acres, while all of the bottom which is capable of yielding even as little as 3 bushels per day, exclusive of the time consumed in culling, covers about 168 acres. In other words, at least 80 per cent of the area is at present commercially worthless.

The observations, in addition to the sounding and chain investigations, on which the foregoing is based, are as follows:

LARKINS ROCK.

This is a small bed in Nansemond River at the extreme southwest corner of Public Ground No. 2. As developed by the survey it has an area of about 39 acres and a depth varying from 4½ to 8 feet at mean low water. It is stated that the product of this bed has been in demand by shucking houses, the size and quality being generally good and the condition fat, especially early in spring. The market oysters found by the survey averaged between 300 and 350 to the bushel and the small oysters about 750 per bushel.

The bed at present bears market oysters at the average density of about 5 bushels per acre, though in spots the production is as high as 18 bushels. The young growth has an average density of about 10 bushels and a maximum of 31 bushels per acre.

At the present time this bed must be regarded as depleted, as at none of the spots examined could a man tong more than 2 bushels of oysters per day, and the average yield, taking the bed as a whole,

would be hardly more than one-half bushel per day. The young growth is sparse and the shells few. The bed bears the aspect of having been carried off bodily for planting purposes, a depredation to which its location makes it susceptible. The results of detailed examinations are as follows:

DETAILS OF EXAMINATION OF LARKINS ROCK.

Station number.	Date of examination.	Mean depth of water.	Character of growth of market oysters.	Oysters caught per square yard.			Estimated quantity oysters per acre.

DRUM SHOAL ROCK.

This is a small bed located at the northwest corner of Public Ground No. 2 in Nansemond County. Its area, density of oyster growth, and estimated contents are as follows:

OYSTER GROWTH ON DRUM SHOAL ROCK.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Scattering	19	92	50	950
Very scattering	14	61	39	546
Depleted	95	62	29	2,755
Total	128			4,251

This bed was doubtless originally restricted to the area of the shoal which is now covered by the scattering and very scattering growth, but oysters and shells have become scattered over the surrounding bottom and it is now connected, by means of a depleted area, with Nansemond Ridge Rock on the south and Newport News Rock on the west.

The scattering growth lies in a depth of from 6 to 8 feet at mean low water and the market oysters grow in such quantity that a tonger of average ability can take about 5 bushels per day. The very scattering growth is at the eastern side of the shoal and has oysters in sufficient numbers to yield about 3½ bushels per day. The density of growth shown for the depleted area in the table produced above is in excess of the actual conditions, as the examina-

tions on which it was based were taken in close proximity to the edge of the shoal, while the more distant bottom is more denuded. The growth of young on the productive part of the rock is fair, being sufficient to yield about 9 bushels per day on the scattered area and about 6 bushels on the very scattered area and about the edges of the shoal.

Following is the record of observations on this bed:

DETAILS OF EXAMINATION OF DRUM SHOAL ROCK.

Station number.	Date of examination.	Mean depth of water.	Character of growth of market oysters.	Oysters caught per square yard.			Estimated quantity oysters per acre.		
				Spat.	Culls.	Counts.	Seed	Market.	Total.

NEWPORT NEWS ROCK.

This lies in the overlapping portions of Public Grounds No. 2, Nansemond County, and No. 6, Isle of Wight County, north of Nansemond Ridge, and between Drum Shoal on the east and Cruiser Rock on the west. Its estimated area, density of growth, and contents are as follows:

OYSTER GROWTH ON NEWPORT NEWS ROCK.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Dense	4	93	108	432
Scattering	27	75	63	1,701
Very scattering	12	83	35	420
Depleted	129	34	27	3,483
Total	172			6,036

The rock in reality consists of several shoal spots separated by areas of depleted bottom in deeper water. The dense area is a small spot lying by itself in about 8 feet of water at low tide, and it bears market oysters in sufficient quantity to yield to the tonger about 9 bushels per day, and the young growth is in nearly the same quantity. The scattered and very scattered growth lies on Cruiser Shoal proper, the former being sufficiently productive to yield about 6 bushels and the latter about 3 bushels per day. On both of these areas there is a fair growth of young, sufficient to yield about 6 bushels per day.

At the eastern edge of the rock, as defined on the chart, there is a dense growth, not shown, which lies just outside of the Baylor line, and running south from this is a growth of young oysters on the so-called depleted bottom sufficient to yield about 4 bushels per day. The depleted bottom on the whole will yield about 2 bushels of market oysters per day and about the same quantity of young.

The following are the results of examinations on this rock:

DETAILS OF EXAMINATION OF NEWPORT NEWS ROCK.

Station number.	Date of examination.	Mean depth of water.	Character of growth of market oysters.	Oysters caught per square yard.			Estimated quantity oysters per acre.

CRUISER SHOAL ROCK.

This rock lies on and about the shoal that gives it its name, mainly in Public Ground No. 6, Warwick County, but partly in the area common to that ground and No. 2, Nansemond County. Its area and condition are shown in the following table:

OYSTER GROWTH ON CRUISER SHOAL ROCK.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Dense	27	140	156	4,212
Scattering	19	47	53	1,007
Very scattering	26	51	28	728
Depleted	32	66	9	288
Total	104			6,235

The dense and scattered areas follow the line of a very shallow ridge which forms the backbone of the shoal, the former being capable of yielding from 10 to 20 bushels of oysters per day and the latter about 5. The area of very scattering growth lies on each side of the more prolific areas and is capable of yielding about 3 bushels of market oysters per day's tonging. The depleted area will yield an average of not over 1 bushel of market oysters per day, and the parts more distant from the ridge are practically bare. Close to the ridge, even on some of the bottom depleted of market oysters, the

growth of young is good enough to yield an average of about 15 bushels per day to the tonger; but on the very scattering and depleted areas further removed from the ridge the young growth is sparse.

The following table shows the results of the examinations made on this bed:

FLAT ROCK AND ADJACENT SMALL BEDS.

Flat Rock is a small bed bearing a dense growth of market oysters lying in the southeast corner of Public Ground No. 6, Warwick County. The examination of this rock was not satisfactory, as owing to an error in platting in the field certain positions supposed to be on the bed proved to be on adjacent planted beds. The single examination, in connection with traversing lines of chain readings, indicates a growth over the entire area which will yield to the tonger an average of about 9 bushels of market oysters per day. There were practically no small oysters or shells, and there was some reason to believe that the place had been planted, though it was fully 200 yards inside of the Baylor lines.

North of Flat Rock is a small depleted area, covering about 7 acres, on which there are about 26 bushels of market oysters and 16 bushels of young oysters per acre, and on which it is computed that a tonger could take not over 2 bushels of oysters per day.

West of Cruiser Rock is another unnamed bed of very scattering oysters. Its area is about 5 acres, with an average of 42 bushels of market oysters and 55 bushels of seed oysters per acre, and it is estimated that a tonger could take about 3½ bushels of oysters per day.

Northwest of Flat Rock, at intervals of about 400 yards, are two small beds where the water does not shoal, on which no determinations were made except with the chain. The indications are of very scattering growths. The areas are about 5 and 2 acres, respectively. The data relating to the several beds examined are as follows:

DETAILS OF EXAMINATION OF FLAT ROCK AND SMALL BEDS BETWEEN NANSEMOND RIDGE AND FISHING POINT.

Station number.	Date of examination.	Mean depth of water.	Character of growth of market oysters.	Oysters caught per square yard.			Estimated quantity oysters per acre.

48	Aug. 12, 1909	10.0	Very scattering	1.8	6.7	2.6	55	42	97
32	Aug. 11, 1909	10.5	Depleted	.0	2.4	1.6	16	26	42

HIGH SHOAL ROCK.

High Shoal Rock is conspicuous from its position, near the middle of James River, surrounding a shoal of sand and broken shells bare at practically all times. The highest part of the shoal is near the channel, from which it extends shoreward toward Fishing Point. The bed, including the depleted parts, is quadrangular in shape, with its more productive areas extending at right angles to the shores along its major diameter. Its extent and density of growth are as follows:

OYSTER GROWTH ON HIGH SHOAL ROCK.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Dense	24	134	90	2,160
Scattering	13	127	48	624
Very scattering	24	58	25	600
Depleted	95	8	8½	807
Total	156			4,191

The dense area extends along practically the entire length of the shoal, as a narrow strip on both sides but especially to the eastward of the highest ridge. The market oysters are somewhat smaller than those in water a little deeper, but on the bed as a whole they were found to average about 400 to the bushel. It is estimated that on this area a tonger could take about 10 bushels of oysters per day.

The area of scattering growth forms a strip on the southern side of the bed along the edge of a deep swash channel which separates it from one of the neighboring Fishing Point Rocks. Market oysters are produced in sufficient abundance to yield the tonger about 6½ bushels per day. The very scattering area lies to the eastward of the dense area and north of the scattering, and produces oysters sufficient to furnish the tonger about 3 to 3½ bushels per day.

The depleted area, which constitutes the major portion of the bed as delineated on the chart, is principally on the western or upstream side, though a strip averaging about 100 yards in width extends around the outer end of the shoal and along its entire eastern side. This area will nowhere yield to the tonger more than about 2½ bushels of oysters per day, and the average yield of all places examined would not be over 1 bushel.

The growth of young oysters on the areas charted as dense and scattering and on the very scattering part closer to the ridge is prolific enough to yield a tonger from 8 to 25 bushels per day, the average of all places examined being about 17 bushels. Clean shells were abundant on the three productive areas and in the depleted area close to the ridge.

The data on which the foregoing statements are based is as follows:

TROUT SHOAL ROCK.

This bed occupies the southeastern part of Naseway Shoal. In its depleted area it is continuous with Dog Shoal Rock, which occupies the upper part of the same shoal, but is separated from the adjacent Fishing Point and High Shoal Rocks by swash channels in which there is an abrupt deepening of the water. The depth ranges from low-water mark to 10 or 11 feet, the greater depths being found in a pocket of deep water which extends far into Naseway Shoal from the westward.

The extent and productiveness of the bed are shown in the following table:

OYSTER GROWTH ON TROUT SHOAL ROCK.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Scattering	25	165	44	1,100
Very scattering	14	118	30	420
Depleted	90	21	8	720
Total	129			2,240

There is no dense growth within the meaning of the definition adopted in this report—that is, bottom on which 8 or more bushels of market oysters may be tonged by a man working 9 hours. There are two areas of scattering growth which lie as strips along the line of a shoal largely exposed at low water. These areas are sufficiently productive to yield from 5 to 10 bushels of market oysters per day to the tonger, the average being about 7 bushels.

The only other productive bottom is a very scattering area occupying the central and eastern portion of the rock, from the ridge to the deep water lying between this shoal and High Shoal. On this area a tonger can average a little over 3 bushels of oysters per day. Depleted areas lie on each side of the shoal, that on the western side being more extensive and continuous with the depleted area of Dog Shoal rock. On these areas a tonger could take hardly a bushel of market oysters per day, although there are spots a little more productive. On the scattering and very scattering areas of market oysters the young growth is prolific, on the former being sufficient to yield to the tonger an average of about 26 bushels per day and on the latter about 16 bushels. On both of these areas there is an abundance of clean shells suitable for taking a set of spat, but the depleted areas have comparatively few shells and young oysters.

The following observations were made on this rock:

DOG SHOAL ROCK.

This bed occupies the northwestern or upstream part of Naseway Shoal. The rocks are in reality two, separated by the tongue of deeper water which makes into Naseway Shoal from the west and extends well toward the ridge of Trout Shoal.

The larger rock is hook shaped and contains two areas of dense growth and a long strip of very scattering oysters, both following the line of a shell ridge bare in parts at low water. The smaller area is a U-shaped ridge of scattering oysters lying between the deeper water just mentioned and the swash channel, which separates if from the adjacent Fishing Point Rock.

The following table shows the area, density of growth, and estimated oyster content of the rock:

OYSTER GROWTH ON DOG SHOAL ROCK.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Dense	16	155	104	1,664
Scattering	13	153	39	507
Very scattering	35	22	27	945
Depleted	118	41	12	1,416
Total	182			4,532

The dense areas produce market oysters in sufficient quantity to yield the tonger an average of about 12 bushels per day, the scattering area will yield about 6 bushels, and the very scattering about 3 bushels. On the depleted area the yield would be at no place more than about 2 or 2½ bushels of marketable stock, and the average at all places examined was about 1 bushel.

The growth of young oysters on this rock is prolific, the density on the dense and scattering areas of market oysters being sufficient to yield the tonger an average of about 23 bushels per day. On the area of very scattering growth the yield should be about 3 bushels of young per day and on the depleted area about 4 bushels. The average of the latter is brought up by the very dense growth of young found in places close to the exposed ridge, where the quantity of market oysters was negligible. Over all of the area shown on the chart as depleted, excepting close to the productive areas, both clean shells and young were practically absent. The market oysters on this rock, like those on Trout Shoal and High Shoal, are comparatively small, averaging a little in excess of 400 per bushel.

The data on which the foregoing description is based are as follows:

FISHING POINT ROCKS.

These are two beds of considerable extent lying between High Shoal and Naseway Shoal and Fishing Point. The names by which they are known to the oystermen were not learned. One of these beds, embracing scattered and very scattered areas, lies between High Shoal and the Baylor line, almost surrounded by deeper water; the other, which includes dense, scattered, and depleted areas, lies along the Baylor line inside of Naseway Shoal, from which it is separated by a channel carrying from 8 to 10 feet at low water.

The statistics of the rocks are as follows:

OYSTER GROWTH ON FISHING POINT ROCKS.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Dense	45	185	119	5,355
Scattering	77	178	82	6,314
Very scattering	47	70	44	2,068
Depleted	90	30	19	1,710
Total	259			15,447

It is estimated that on the dense area a tonger could take an average of 10 or 11 bushels of market oysters per day and on the scattering area about 7 bushels. On the very scattering area the water is rather deep, the beds in this vicinity ranging from about 12 to 22 feet at low water, and although the density of growth is fair as compared with other beds described, this reduces the probable yield to the tonger to an average of between 3 and 4 bushels per day. On the depleted

area the probable average yield is estimated at between 1½ and 2 bushels per day of tonging. On the area of scattering growth on the bed inside of High Shoal young growth is almost absent, giving the bottom the appearance of having been planted. On the very scattering area in the same bed the quantity of young is sufficient to yield about 6 bushels per day per tonger.

On the dense and scattering areas of the other bed there is a dense growth of young oysters, sufficient to yield on the former about 18 bushels and on the latter about 13 bushels per day. On the depleted bottom as a whole it would probably be impossible to take more than 3 bushels of young per day, though there are spots where the yield might be double that amount.

The following results were obtained from examinations:

ROCKS BETWEEN FISHING POINT AND BALLARDS MARSH ROCKS.

In this region there are two small rocks for which no names were obtained. One of these lies close to the Baylor line and is encroached on by planted areas. It consists of a dense area inshore, the oysters becoming very scattering farther out, surrounded by a fringe of depleted bottom. The other bed is a small patch of very scattering growth about 400 yards farther out, in the direction of Dog Shoal Rock.

The following table exhibits the extent and condition of these beds:

OYSTER GROWTH ON ROCKS BETWEEN FISHING POINT AND BALLARDS MARSH ROCKS.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Dense	5	183	268	1,340
Very scattering	8	1	31	248
Depleted	18	0	0	0
Total	31			1,588

The dense area varies considerably in productiveness, one spot near what appeared to be the center of the original bed producing a quantity of oysters sufficient to yield 50 bushels per day to the tonger, while in another place not more than 9 bushels could be taken.

On the very scattering area of the larger bed barely 3 bushels per day could be taken, but on the small isolated spot the growth was sufficient to yield about 4 bushels per day. The depleted area is practically bare of oysters of all sizes, and the quantity of shells is negligible. On the small strip in the dense bottom where the market oysters were most abundant there is a very dense growth of young, but the rest of the bed is deficient in this respect.

The following table gives the results of the several examinations of the beds:

DETAILS OF EXAMINATION OF BEDS BETWEEN FISHING POINT AND BALLARDS MARSH ROCKS.

Station number.	Date of examination.	Mean depth of water.	Character of growth of market oysters.	Oysters caught per square yard.			Estimated quantity oysters per acre.

BALLARDS MARSH ROCK.

This is the bed called by Winslow "Bally Smash," probably an unconscious attempt to render a provincial pronunciation phonetically. It is the westernmost bed of Public Ground No. 6, Isle of Wight County. It follows the line of a shoal which sets offshore from Ballards Marsh.

Its extent and condition are epitomized in the following table:

OYSTER GROWTH ON BALLARDS MARSH ROCK.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Scattering	4	152	31	124
Very scattering	33	191	24	792
Depleted	142	45	7	894
Total	179			1,810

The scattering area is a small spot near the inner end of the shoal, where the quantity of market oysters is sufficient to yield to the tonger between 7 and 8 bushels per day. The very scattering growth is found on each side of this and beyond it for a distance of about two-thirds the length of the shoal, bearing a growth yielding about 3½ bushels of oysters per day's work. On both sides of the very scattering area and beyond it along the line of the shoal is a depleted bottom on which, as a whole, less than 1 bushel of oysters can be taken per day, the edges of the area being practically barren.

Along both sides of the shoal, even on the so-called depleted bottom which surrounds it at its outer end, is a heavy growth of young and many shells, which will yield on the average about 35 bushels of culls and spat per day. The market oysters on this bed will average about 400 to the bushel and the culls or seed oysters about 750.

CREEK CHANNEL ROCK.

This is a small bed about 2 acres in extent, covering a shoal marked by a buoy of the Light-House Establishment. It has the indications of having been a dense bed, but at the present time it is depleted, and a tonger could take on it an average of hardly a bushel of oysters per day, and the young growth is still more sparse. It is surrounded by private beds. It constitutes Public Ground No. 5, Isle of Wight County.

The following observations were made on this bed:

DETAILS OF EXAMINATION OF CREEK CHANNEL SHOAL ROCK.

Station number.	Date of examination.	Mean depth of water.	Character of growth of market oysters.	Oysters caught per square yard.			Estimated quantity oysters per acre.		
				Spat.	Culls.	Counts.	Seed.	Market.	Total.
		Feet.					*Bushels.*	*Bushels.*	*Bushels.*
383	Aug. 26, 1909	13.0	Depleted	0.0	0.0	1.4	0	19	19
384	do	6.0	do	0.0	1.1	.2	7	3	10

AARON SHOAL ROCK.

This is the only bed in Public Ground No. 2, Isle of Wight County. It is almost or quite surrounded by private beds, the boundary stakes of which formed a forest which made it difficult to tell, without spending on the bed more time than its importance warranted, what was planted ground and what was not.

The following statistics exhibit its present condition:

OYSTER GROWTH ON AARON SHOAL ROCK.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Dense	2	129	100	200
Scattering	4	135	33	132
Very scattering	3	0	23	69
Depleted	24	112	5	120
Total	31			521

The dense area forms a very narrow strip along the northern edge close to and among the stakes. Its area could not be very definitely determined without wasteful expenditure of time, but is probably about 2 acres. About 10 bushels of oysters per day could be taken by the tonger.

On the scattering growth it is estimated that about 4½ bushels, and on the very scattering about 3 bushels, per day could be taken. The depleted area is for the most part bare. There is a good growth of young on the dense and scattered areas and at two spots on the depleted bottom.

The following examinations were made:

DETAILS OF EXAMINATION OF AARON SHOAL ROCK.

Station number.	Date of examination.	Mean depth of water.	Character of growth of market oysters.	Oysters caught per square yard.			Estimated quantity oysters per acre.

BROWNS SHOAL ROCKS.

Included under this name are a number of small rocks, separated by depleted and barren bottom lying at the extreme lower end of Public Ground No. 1, Warwick County, just above Newport News. The productive portions lie on Browns Shoal and a number of other shoal spots in the vicinity. The extent and present condition of the rocks as a whole are shown in the following table:

OYSTER GROWTH ON BROWNS SHOAL ROCKS.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Dense	68	126	183	12,444
Scattering	44	142	54	2,376
Very scattering	27	88	39	1,053
Depleted	226	5	4	904
Total	365			16,777

The dense area is found in seven patches, of which the largest, covering about 25 acres, is on a shoal west of Browns Shoal surrounding a watchhouse or covered pierhead. The areas as a whole are quite productive of market oysters, and it is estimated that an industrious tonger working nine hours per day could take between 10 and 40 bushels of oysters, the average at all places examined being about 15 bushels.

The areas of scattering growth are three in number, lying on the ends of Browns Shoal proper and a small shoal west of it, inshore of the watchhouse above alluded to. They carry a depth of between about 4 or 5 and 12 feet at low water, and their productiveness is such that a tonger could take an average of between 5 and 6 bushels of market oysters per day.

The areas of very scattering growth are a number of small patches nearly all lying between the more prolific areas and the edges of the bed. They are nearly all covered by about 10 feet of water at low tide, and bear oysters in sufficient quantity to yield to the tonger between 3 and 4 bushels per day.

The depleted bottom constitutes nearly two-thirds of the total area of the beds as charted. At no place does it promise to yield during the present season more than 2½ bushels per day, and the major part of it is practically barren.

The growth of young oysters is very good on the shallower parts of the beds, especially on those portions yielding a scattering growth of market stock, where a tonger could take an average of about 15 bushels per day. On the dense areas as a whole the young growth is less abundant, the estimated average yield being about 11 bushels per day, the heaviest growth being on two small shoals between the inner end of Browns Shoal and the shipyard at Newport News.

On all of the productive areas there is an abundance of shells suitable for catching a set of spat, but the depleted areas are practically bare and give no promise of recuperation under any natural conditions.

The following exhibits the results of examinations:

GUN ROCK.

This is a small bed lying on a shoal spot west of the preceding. Its extent and estimated density of growth and contents are as follows:

OYSTER GROWTH ON GUN ROCK.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Dense	6	198	152	912
Very scattering	16	62	30	480
Depleted	4	0	0	0
Total	26			1,392

The dense area forms a narrow tongue running along the inner or shoreward end of the ridge or backbone of the shoal, and it produces market oysters in sufficient quantity to yield the tonger about 9 bushels per day. There is no scattering growth, but the outer half of the length of the bed as far as the Baylor line produces a very scattering growth sufficient to yield about 3 bushels per day.

Along the higher parts of the ridge, on both the dense and very scattering bottoms, there is a prolific growth of young oysters, sufficient to furnish the tonger from 12 to 14 bushels per day. The edges of the very scattering area produce but few young oysters, and the depleted bottom is practically bare of both oysters and clean shells, its position being indicated solely by the presence of shells more or less deeply buried in the mud.

The following observations were made:

KETTLE HOLE ROCK.

I am not certain of the name of this bed, as in the field some confusion arose as to whether this or the next was Thomas Point Rock. In designating it as above I have been guided by Winslow's nomenclature. This bed is the largest and most important in this part of

the river. It lies on the north side of a shallow ridge, extending thence shoreward toward Watts Creek as far as the Baylor line.

Its extent and present general condition are as follows:

OYSTER GROWTH ON KETTLE HOLE ROCK.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Dense	258	317	105	27,090
Scattering	66	207	82	5,412
Very scattering	111	180	42	4,662
Depleted	11	0	0	0
Total	446			37,164

The principal area of dense growth starts from the ridge and extends as a broad belt as far as the Baylor line inshore. The public ground includes but a portion of the shoal, possibly because the southern part was taken up as private ground prior to the Baylor survey. The productive bottom probably extends across the ridge, but as it is not included in the public grounds and is staked as a private holding it was not examined. The growth of market oysters on the public ground is rather uniform and is sufficient to provide the tonger with from 8 to 13 bushels per day, the average being about 9 or 10. Near the middle of the inner part of the dense area is a small spot where market oysters are deficient in quantity, but the growth of young is so prolific that it has not been thought advisable to differentiate it on the chart. There is also a small area of dense growth on a shallow spot east of the main area.

The scattering growth on Kettle Hole Rock forms a fringe along the western border of the dense area, with a broad tongue thrust into the latter near its middle. The growth of market oysters is sufficient to yield to the tonger an average of about 6 bushels per day.

The areas of very scattering growth form a border on the eastern and inshore edges of the dense growth, and it is estimated that about 3 or 3½ bushels of oysters could be tonged per day on the areas taken in their entirety.

The depleted bottom is insignificant and bare of everything except a few buried shells.

There is a heavy growth of young oysters over practically the entire extent of this bed. On the dense areas they are estimated to be present in sufficient quantities to yield to the tonger about 28 bushels per day as an average at the beginning of the season, while on the scattering and very scattering areas the yield would probably average about 16 or 17 bushels. Undoubtedly the entire bed can be regarded as

presently and prospectively productive. The following data were obtained from the examinations made:

THOMAS POINT ROCK.

As explained in the discussion of the preceding bed, there may be some question as to the name of this one, which lies between what has been called Kettle Hole Rock and Blunt Point Rock. It is entirely separated from the former by a swash channel carrying from 12 to 21 feet of water, but is connected with Blunt Point Rock by a narrow ridge of depleted bottom. The bed lies on and about two shoals which extend from the edge of the channel lying north of White Shoal Light. Its extent and condition are as follows:

OYSTER GROWTH ON THOMAS POINT ROCK.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Dense	76	108	115	8,745
Scattering	118	170	71	8,378
Very scattering	100	103	51	5,100
Depleted	127	80	21	2,667
Total	421			24,890

The dense growth of market oysters is in three patches, all lying on or close to the shoaler parts of the bed in water ranging from 5 to 8 feet at low tide. The growth is sufficiently prolific to yield to the tonger about 10 bushels of marketable oysters per day.

The area covered by scattering marketable oysters stretches from the western side of the longer shoal across some intervening deeper water to two small shoals to the westward. Over the whole area the density of growth is such that about 6 bushels of oysters may be taken per day.

The very scattered growth is in three areas fringing the denser parts of the bed. Its productiveness varies between areas which will yield 2½ and those which will yield 4½ bushels per day, the general average at all places examined being about 3½ bushels.

The best of the depleted bottom, which is in the areas lying on the edge of the deep-water channel, will yield about 2½ bushels per day, while the inshore area and that lying in the midst of the scattering growth will not yield an average of over 1 bushel.

The young growth is in good quantity, though not so abundant as on Kettle Hole Rock. On the dense and scattering areas it is sufficient to yield an average of about 15 bushels per day. On the very scattering area near the inshore end of the eastern edge of the rock it is in about the same abundance, but elsewhere it will yield not more than 4½ bushels per day's tonging. On the best of the depleted bottom, along the edge of the deep-water channel, it is estimated that about 10 or 11 bushels per day could be taken by the tonger, but on other parts of the depleted area young oysters are practically absent.

The oysters on this bed, as on all others on this shore of the river, are of fair size, the marketable stock averaging about 350 per bushel and the young approximately 750.

The following observations were made:

BLUNT POINT ROCK.

This is the uppermost bed in that part of Public Ground No. 1, Warwick County, in which the cull law is enforced. All beds above this, excepting the small one in Warwick River, are within the area which is set apart for seed production. This rock is rather attenuated in most of its parts, being in the shape of an irregular ring surrounding a deeper barren area, with a long tail running along the Baylor line in the direction of Deep Creek. The highly productive area is very limited and the very scattering growth constitutes more than half of the total area. The extent and general condition of the bed at the time of the survey are shown in the following table:

OYSTER GROWTH ON BLUNT POINT ROCK.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Dense	16	171	161	2,576
Scattering	69	193	60	4,140
Very scattering	225	105	45	10,125
Depleted	118	42	1¼	1,652
Total	428			18,493

The bottom covered with a dense growth occurs on two small patches on small shoals, on which about 15 bushels of market oysters could be taken in a day.

There are three areas of scattering growth, of about equal productiveness so far as market oysters are concerned. One of these is at the extreme end of the rock off Deep Creek, which is in close proximity to planted beds and bears some indications of being itself planted ground. These areas as a whole will yield, it is estimated, an average of about 6 bushels per day.

The very scattering growth consists of a narrow zone almost encircling the included barren area above alluded to and a prolongation northward toward Deep Creek. The examinations made on it indicate a probable yield of about 3¼ bushels per day of continuous tonging.

The depleted area skirts the preceding for a good part of its length, and in addition forms a projection on the western part of the bed and a small isolated patch on a shoal just beyond it. Its content of oysters is such that it could furnish the tonger with hardly more than a bushel per day.

The young growth is in good quantity on the dense and scattering areas of oysters, excepting that nearest Deep Creek, where it is practically absent. With the exception noted, the tonger should be able to gather about 15 bushels per day. On the narrow annular part of

the beds the production of young oysters is good on the very scattering and depleted areas, which in their other parts are deficient in immature growth.

The following data furnish the basis for the foregoing:

WHITE SHOAL ROCKS.

These are two rocks in very shallow water, with slightly greater depths between and deep channels surrounding. The westernmost lies about a bare shell bank and the easternmost is nearly awash at low water.

The following exhibits their extent and condition at the beginning of the oyster season of 1909–10.

OYSTER GROWTH ON WHITE SHOAL ROCKS.

Character of growth of market oysters.	Area.	Oysters per acre.		Estimated content of market oysters.
		Seed.	Market.	
	Acres.	*Bushels.*	*Bushels.*	*Bushels.*
Dense	44	312	127	5,588
Very scattering	10	108	36	360
Depleted	52	53	12	624
Total	106			6,572

The dense areas produce a good quantity of marketable oysters and at the beginning of the present season should be capable of yielding about 12 bushels of oysters per full day of tonging. There are no areas of scattered growth within the definition of this report, but at

each end of the western rock there is a small patch of very scattering growth capable of yielding an average of 3½ bushels of marketable oysters per day.

The area charted as depleted bears very few marketable oysters.

The young growth on the dense areas is very prolific, being in sufficient quantity to afford a daily return to the tonger of about 35 bushels. On the scattering bottom about 10 bushels per day could be taken, while on the depleted bottom as a whole the average would hardly exceed 4 bushels, although two or three times that many could be taken in places.

SEED OYSTER AREA.

JAIL ISLAND ROCK.

For this and all of the following rocks the standard of density of growth is different from that adopted in the preceding descriptions. The cull law, so far as it relates to the size of oysters, does not apply, and oysters of whatever size may be taken. The entire content of the bed, both young and old, is therefore taken into consideration, and as the average price of seed oysters is about two-thirds of that of the market oysters from the James River, a larger quantity has to be taken to furnish a living wage. In all of the following descriptions a bed is regarded as dense when 12 or more bushels may be taken by a tonger in a day's work, as scattering when it will yield between 8 and 12 bushels, very scattering when it yields between 4 and 8, and depleted if less than 4 bushels can be tonged per day. As the market oysters sell for 45 cents and the seed oysters for but 30 cents per bushel, the financial return is essentially equal.

Jail Island Rock, which extends alongshore west of the mouth of Warwick River, is continuous at its offshore edge with Wreck Shoal

OYSTER GROWTH ON JAIL ISLAND ROCK.

Rock, the boundary between them as adopted in this report being purely arbitrary.

The extent and general condition of the bed at the time of the survey was as follows:

OYSTER GROWTH ON JAIL ISLAND ROCK.

Character of growth.	Area.	Oysters per acre.	Estimated content of oysters.
	Acres.	*Bushels.*	*Bushels.*
Dense	227	143	32,461
Scattering	198	109	21,582
Very scattering	14	28	392
Depleted	508	8	4,064
Total	947	.....	58,499

The principal area of dense growth runs from the inner edge of Wreck Shoal Rock in a gradually narrowing belt to a tongue extending to within 200 or 300 yards of shore between Jail Island and the mouth of Warwick River. The depth of water gradually decreases from about 9 feet to 2 or 3 feet at low water, near Jail Island. There is also a small area of dense growth lying on an isolated patch in about 10 or 11 feet of water off the mouth of Warwick River, which, being just on the cull line, is arbitrarily included in the Jail Island bed for the purposes of this report. The dense bottom as a whole will afford the tonger an average catch per day of about 17 bushels of oysters of all sizes.

The area of scattering growth lies in a single body north and west of the preceding in from 6 to 11 feet of water. The growth on the whole is rather heavier in the deeper water, and as an average should yield approximately 9 bushels per day.

The very scattering growth is in a small patch immediately east of Jail Island, where the yield to the tonger should be about 5 bushels per day.

The depleted bottom forms a broad zone on the inshore side and a narrow strip on the eastern edge of the bed. There is also a depleted area adjoining the small, isolated, dense patch before described, and a small patch lying between that and the main bed. In most places the so-called "depleted bottom" is practically bare. There is but a moderate supply of shells on the dense area and on the scattering area close to it, but elsewhere the bed is deficient in this respect.

It is stated that the inshore portions of the bed, on the depleted bottom along the Baylor line, produce fine single oysters, which in calm weather are picked up one by one and bring a high price in the markets. The survey did not disclose any quantity of such oysters.

WRECK SHOAL ROCK.

This is a large, important, and productive bed extending from the preceding to the edge of deep water. For the purposes of this report, it is regarded as including the oyster growth on and about Wreck Shoal proper and the small shoal to the westward of its outer end. Excepting where it adjoins Jail Island bed, its boundaries are rather sharply defined by a sudden shoaling of the water. This is especially pronounced at the southern edge of the bed, where the bottom very abruptly rises from about 150 feet to within 6 feet of the surface. North of the smaller shoal the bed is prolonged into a narrow belt occupying a slightly shoaling ridge connected with a corner of Mulberry Swash Rock. The depth at low water varies from less than 5 feet on the shoals to 12 or 15 feet at the edges. On one small area projecting as a tongue from the southeast side the water reaches a maximum depth of 30 feet.

Wreck Shoal Rock is practically everywhere highly productive and no part of it falls below the standard here regarded as constituting denseness of growth. Accepting the arbitrary inner boundary here adopted, it has an area of about 506 acres. The oyster growth at the places examined ranges from 178 to 497 bushels per acre, the average being about 316. The heaviest growth is as a rule found on the shoaler places, which facilitates the removal of the product. This materially raises the average daily yield to the tonger, which ranges in different places from 12 bushels to 51 bushels, with a general average for the entire bed of over 29 bushels.

The bottom is well covered with clean shells and the bed can be regarded as being in a healthy and promising condition. In a few places there is a fair growth of large oysters and on the bed as a

whole the young growth over 1 inch in length is numerically more than double that under 1 inch.

The following table exhibits the data obtained from the several examinations made:

DRY SHOALS ROCKS.

These are 5 small rocks lying west of the preceding on and about shoals which ebb nearly or quite bare. They are in general isolated and surrounded by deep water, though two of them are connected by narrow ridges of depleted bottom with Swash Rock and Mulberry Swash Rock, respectively.

Their present condition and extent are shown in the following table:

OYSTER GROWTH ON DRY SHOALS ROCKS.

Character of growth.	Area.	Oysters per acre.	Estimated total content of oysters.
	Acres.	*Bushels.*	*Bushels.*
Dense	126	244	30,766
Scattering	18	124	2,232
Very scattering	9	85	765
Depleted	21	20	420
Total	174	.....	34,183

Four of these rocks are composed wholly or in major part of bottom bearing a dense growth of oysters, while the fifth, the smallest, bears a scattering growth exclusively. The dense growth in its daily yield to the tonger varies, with the locality, between 13 and 59 bushels, the average density over the entire area being sufficient to permit a

daily catch of about 30 bushels per man. The average depth of water is about 5 to 7 feet at low tide.

The scattering growth is found in two places, one an isolated rock of small size and the other at the extremity of a larger bed where the productive bottom runs off to deeper water. There is not much difference in the density of the growth on the two places, and it is estimated that on the two a tonger could take an average of about 10 bushels of oysters per day.

The very scattering bottom lies in two small patches at opposite ends of the longest bed of the group, and the growth is so sparse as barely to remove the areas from the category of depleted bottom. The depleted areas are three in number, one in the deeper water at the tip of a rock and the others on the two connecting ridges mentioned earlier in this description. About the same numerical proportion exists between the culls and spat as on the preceding bed, and at one place on the dense area there is a good growth of marketable oysters averaging between 400 and 450 per bushel. There is a fair or good deposit of shells throughout the dense and scattering areas and on the apical area of very scattering growth, but elsewhere the rocks are deficient in this respect.

POINT OF SHOALS ROCK.

This name is here given to a large area of varying productiveness lying between the preceding, Long Shoal and Point of Shoals Lighthouse, but it is possible that the name as used by the oystermen may not strictly accord with this usage. Scattered over the area are a number of small shoals ebbing nearly or quite bare, but the average depth is in general between 6 and 8 feet. Excepting at its northern edge, where an imaginary line separates it from Long Shoal Rock,

the bed is everywhere bounded by the deep water of the ship channel or a swash channel which separates it from Dry Shoals and Swash Rocks. Where it faces the ship channel there is for most of the distance a border of barren bottom lying between the bed proper and deep water.

The condition and extent of the bed at the time of the survey was as follows:

OYSTER GROWTH ON POINT OF SHOALS ROCK.

Character of growth.	Area.	Oysters per acre.	Total content of oysters.
	Acres.	*Bushels.*	*Bushels.*
Dense	254	200	50,800
Scattering	155	93	14,415
Very scattering	239	42	10,038
Depleted	142	15	2,130
Total	790		77,383

The dense areas are three, one near the eastern end of the bed, another adjoining the corresponding area of Long Shoal Rock, and the third an isolated spot on a shoal in the swash channel. The densest growths occur as a rule on the shoaler spots, especially at the eastern end of the bed, from the isolated area above alluded to to the ship channel. In this area the average growth is about 275 bushels of oysters to the acre—considering the depths, sufficient to yield about 38 bushels per day's tonging—while the average of the whole area of dense growth would not exceed 25 bushels per day.

There are four scattering areas, one of which, near the eastern apex of the bed, is insignificant. On these as a whole a tonger should average, at the beginning of the season, about 10 bushels per day.

The very scattering growth is distributed in three areas, of which one adjoins the dense growth on the isolated patch in the swash channel. They are barely prolific enough to raise them above the assumed limit of depletion.

The depleted area is in five patches or borders along the free boundary of the bed. They are entirely negligible in their productiveness.

On the dense and scattering areas the proportion of very small to small oysters is higher than on the beds previously described, and there are several places on each where the growth of oysters above 3 inches long is fair.

On the dense areas the deposit of shells is abundant, on the areas of scattering growth it is ample, while the areas with a very scattering growth and the depleted bottoms are decidedly deficient. In general the latter two areas are of no present and little prospective value.

SWASH ROCK.

This bed lies inshore of the preceding, nearly surrounded by swash channels. It is connected by narrow isthmuses with Long Shoal and Dry Shoal Rocks and adjoins V Rock to the westward. It consists of a dense area surrounding two shoals ebbing bare, and two depleted areas which connect it with adjoining beds.

Its condition and extent in August, 1909, was as follows:

OYSTER GROWTH ON SWASH ROCK.

Character of growth.	Area.	Oysters per acre.	Estimated total content of oysters.
	Acres.	*Bushels.*	*Bushels.*
Dense	146	293	42,778
Depleted	115	15	1,725
Total	261	.....	44,50

The dense area as a whole is prolific in its product, but the middle part of the bed, between the shoals pots, is less densely covered than the surrounding area. It is estimated that at the beginning of the season a tonger could take an average of about 39 bushels of oysters per day. The covering of clean shells is sufficient to guarantee a good strike under favorable conditions. The depleted bottom is practically bare of oysters and shells and is at present and potentially worthless under natural conditions.

The following examinations were made during the survey:

DETAILS OF EXAMINATION OF SWASH ROCK.

Station number.	Date of examination.	Mean depth of water.	Character of growth.	Oysters caught per square yard.			Estimated quantity oysters per acre.
				Spat.	Culls.	Counts.

MULBERRY SWASH ROCK.

This is a long narrow bed lying between Swash and V rocks on the outside and the so-called Marshy Island Rock on the shoreward side. At its southeastern end it is connected by narrow strips of indifferent productiveness with Wreck Shoal and Dry Shoal rocks, and its offshore boundary is the edge of the deep swash channel running toward Mulberry Point.

It consists essentially of bottom carrying a dense growth, interrupted at two places by areas of inferior productiveness. Its condition and extent in the latter part of August, 1909, are shown in the following table:

OYSTER GROWTH ON MULBERRY SWASH ROCK.

Character of growth.	Area.	Oysters per acre.	Estimated total content of oysters.
	Acres.	*Bushels.*	*Bushels.*
Dense	422	302	127,444
Scattering	34	106	3,604
Very scattering	20	130	2,600
Depleted	29	43	1,247
Total	505		134,895

The dense area bears a growth varying from 161 to 570 bushels per acre, and the depths vary from 8 to upward of 20 feet. The heavier growth is as a rule in the shoaler water, though this rule is not without exceptions. It is estimated that a tonger could take an average of about 23 bushels per day at the beginning of the season.

The scattered area is limited in extent and bears a growth of between 88 and 117 bushels per acre, in a depth of between 13 and 15 feet, and it is estimated that it will yield about 8 bushels per day.

The area of very scattering growth connects this bed with Wreck Shoal Rock, and although, as shown by the foregoing table, the growth is heavier than on the preceding area, it lies in between 18 and 20 feet of water and will therefore be less productive to the tonger, its estimated initial yield being about 7 bushels per day. The depleted area is in several small patches.

There is an abundant supply of shells on the dense area, a quantity of doubtful sufficiency on the bottoms bearing scattering and very scattering growths, and a deficiency on the depleted bottom.

MARSHY ISLAND ROCK.

This lies between Mulberry Swash Rock and the inshore boundary of the public ground, principally in the "addition" which was made a part of the ground subsequent to the Baylor survey. The name here employed is coined for the purpose of this report, as the name by which this area of oyster bottom is known to the oystermen, if it has a distinctive name, was not ascertained by the survey. The outer or offshore boundary of the bed is defined more or less sharply by a channel, carrying a maximum of from 21 to 27 feet of water, between this and Mulberry Swash Rock.

The condition and extent of this bed about the middle of August, 1909, was as follows:

OYSTER GROWTH ON MARSHY ISLAND ROCK.

Character of growth.	Area.	Oysters per acre.	Estimated total content of oysters.
	Acres.	*Bushels.*	*Bushels.*
Dense	197	231	45,507
Scattering	322	129	41,538
Very scattering	235	85	19,975
Depleted	387	18	6,966
Total	1,141		113,986

The dense areas lie in three isolated patches which exhibit no material shoaling over the surrounding bottom, except where they touch the channel which bounds the bed offshore. The depth of water on

the several areas ranges between 6 and 16 feet, and the density of growth between 142 and 410 bushels per acre. It is estimated that the bottoms are capable of producing an initial yield of about 18 bushels per day.

The scattering area occupies a general central position in the bed surrounding one of the dense spots. The depth varies from 10 feet inshore to about 22 feet at the edge of the channel, and the quantity of oysters varies between 92 and 186 bushels per acre. The estimated daily yield to the tonger is about 10 bushels.

The bottom covered by a very scattering growth forms a zone encircling the inner edge of the preceding. It lies in a depth varying from 7 to 16 feet, and, although the examinations were not as numerous as they should have been, they indicate that the growth is sufficient to yield an average of between 6 and 7 bushels per day.

The depleted bottom lies in a belt on the inside edge of the bed. It is practically bare of oysters and shells.

Shells are found in fair quantities on the dense bottom and on the outer parts of the scattering growth, but are deficient on the inshore parts of the latter, on most of the area of very scattering growth, and on the depleted area.

The following observations were made:

LONG SHOAL ROCK.

This triangular bed flanks a shoal, ebbing bare in many places, which extends eastwardly from Point of Shoals lighthouse for a distance of upward of 1½ miles. As understood in this report, its boundary is an imaginary line running from Point of Shoals light toward Jail Island at an average distance of about 300 to 400 yards from the crest of the shoal, as far as the swash channel opening toward the northwest, along the edge of this channel to its mouth, and thence to the starting point. The main body of the rock, therefore, lies north of the crest of the bar. Its condition and extent about the beginning of September, 1909, were as follows:

OYSTER GROWTH ON LONG SHOAL ROCK.

Character of growth.	Area.	Oysters per acre.	Estimated total content of oysters.
	Acres.	*Bushels.*	*Bushels.*
Dense	331	241	79,771
Scattering	10	64	640
Very scattering	84	60	5,040
Depleted	79	16	1,264
Total	504		86,715

A dense growth of small oysters, with a good proportion of larger ones in a few spots, covers the major part of the bed. At various places the total growth varies between 148 and 364 bushels per acre, and it is estimated that at the beginning of the season a tonger could take about 28 bushels per day.

The scattering growth is comprised in one small spot about 100 to 200 yards from the lighthouse, where about 9 bushels per day may be taken.

The very scattering growth lies in two small patches along the western border of the bed and a larger area south of the ridge is continuous with similar bottom on Point of Shoals Rock. It is capable of yielding between 6 and 7 bushels per day. The depleted area lies south of the outer half of the ridge, with a small patch on the swash channel. It is practically bare of oysters and shells.

The areas bearing oysters in dense and scattering growth are covered with a supply of shells amply sufficient to serve the purposes of cultch. The small patches of very scattering growth are also fairly covered, but the large area south of the ridge and the depleted area adjoining are deficient.

The following observations were made:

V ROCK.

This bed takes it name from the shape of a bare shoal near its southwestern edge. It is inshore of the preceding rock and adjoins Swash Rock to the southeast.

The area and character of growth on the bed are epitomized in the following table:

OYSTER GROWTH ON V ROCK.

Character of growth.	Area.	Oysters per acre.	Estimated total content of oysters.
	Acres.	*Bushels.*	*Bushels.*
Dense	240	227	54,480
Very scattering	73	84	6,132
Depleted	73	15	1,095
Total	386		61,707

The dense area occupies the middle belt of the bed and carries a growth of between 144 and 344 bushels per acre, the average estimated yield per day to the tonger being about 21 bushels.

The very scattering growth lies along the northwestern edge of the bed and on a comparatively shallow ridge along the swash channel near its mouth. It bears oysters in a quantity to yield about 7 bushels per acre.

The depleted area adjoins similar bottom on Swash Rock and is practically bare of both oysters and shells. The supply of shells on the rest of the bed is ample to secure their reseeding under proper conditions.

The data for the bed are as follows:

DETAILS OF EXAMINATION OF V ROCK.

MOORES ROCK.

The bed known to the oystermen by this name lies on a shoal surrounded by deep water about halfway between Point of Shoals Light-House and Mulberry Point. It consists principally of bottom bearing a dense growth, with a scattering fringe along the southern half of its western edge. Its general extent and condition are as follows:

OYSTER GROWTH ON MOORES ROCK.

Character of growth.	Area.	Oysters per acre.	Estimated total content of oysters.
	Acres.	*Bushels.*	*Bushels.*
Dense	37	265	9,805
Scattering	6	168	1,008
Total	43	.....	10,813

On the dense area the oysters, as developed by the survey, range between 134 and 351 bushels per acre, and it is estimated that the bottom as a whole will produce about 28 bushels of oysters per day of tonging.

The area of scattering growth lies in the deeper water close to the adjoining barren bottom, and its estimated yield to the tonger is about 8 bushels per day. The deposit of shells is good over the entire area of the bed.

HORSEHEAD ROCK.

This bed covers several shoals along the edge of deep water south of Mulberry Point, and for the purpose of this report is considered to include a small patch close to the Baylor line to the eastward. The apex of the bed is detached, but the remainder is continuous, though of varying productiveness. East of this rock and north of Marshy Island Rock the survey found small patches of oysters close to the Baylor line, adjoining or included in various planted beds. This region is shown on the charts, included within red lines but without shading.

The general distribution of oysters on Horsehead Rock is as follows:

OYSTER GROWTH ON HORSEHEAD ROCK.

Character of growth.	Area.	Oysters per acre.	Estimated total content of oysters.
	Acres.	*Bushels.*	*Bushels.*
Dense	33	223	7,359
Scattering	192	104	19,968
Very scattering	139	112	15,568
Depleted	16	0	0
Total	380		42,895

The areas of dense growth are on the terminal isolated shoal and in two small patches on the main part of the bed. The growth varies between 178 and 283 bushels per acre, and it is estimated that the area as a whole will yield an average of 20 bushels per day to the tonger at the beginning of the season.

On the areas of scattering oysters the density of growth is between 47 and 170 bushels per acre, and it is estimated that they are capable of yielding, at the beginning of the season, an average of about 7 bushels per day per tonger.

On the bottom which is rated as carrying a very scattering growth the average per acre is slightly higher than on the preceding, but as the water is deeper it is less productive in its return per day of labor expended on it.

The depleted bottom lies inshore, close to Mulberry Point, and is practically, in many cases absolutely, bare of oysters and almost as deficient in shells. On all other areas the deposit of shells is good or fair.

DEEPWATER SHOALS ROCK.

This is considered as including all oyster bottoms within the Baylor lines above Mulberry Point. Its condition and extent are as follows:

OYSTER GROWTH ON DEEPWATER SHOAL ROCK.

Character of growth.	Area.	Oysters per acre.	Estimated total content of oysters.
	Acres.	*Bushels.*	*Bushels.*
Dense	17	129	2,193
Very scattering	21	57	1,097
Depleted	241	12	2,892
Total	279	.....	6,182

The comparatively small productive area on this bed all lies within a radius of about 1,000 yards of Deepwater Shoals Light-House, most of it being in the immediate vicinity of the light. The dense area is in two small patches on which there is a sufficient growth to yield an average maximum of about 15 bushels per day of actual tonging.

The very scattering areas are three in number, all more or less intimately associated with the preceding. They should yield about 6 bushels per day at the beginning of the season.

The depleted area is practically devoid of oysters. On the areas of dense and very scattering growth there is a good covering of shells, and they are also found in ample numbers on the depleted area within a radius of 1,000 or 1,200 yards of the light, but elsewhere the bed is practically denuded.

The following examinations were made:

ROCK WHARF SHOALS ROCK.

This bed lies near the western end of Public Ground No. 1, Isle of Wight County, across the river from the group of seed beds previously described. It forms two patches surrounding shoals and consists principally of productive bottom, as shown in the following table:

OYSTER GROWTH ON ROCK WHARF SHOALS ROCK.

Character of growth.	Area.	Oysters per acre.	Estimated total content of oysters.
	Acres.	*Bushels.*	*Bushels.*
Dense	18	140	2,520
Depleted	8	11	88
Total	26	.....	2,608

The dense area should yield an average of about 22 bushels of oysters per day, and is fairly covered with clean shells. The depleted bottom is practically bare of both oysters and shells.

BEDS BETWEEN ROCK WHARF SHOALS AND SPINDLE ROCK.

These cover the largest area of productive bottom in the ground, distributed in three patches. Their aggregate area and extent are as follows:

OYSTER GROWTH ON BEDS BETWEEN ROCK WHARF SHOALS AND SPIND E ROCK.

Character of growth.	Area.	Oysters per acre.	Total content of oysters.
	Acres.	*Bushels.*	*Bushels.*
Dense	45	140	6,300
Very scattering	5	46	230
Depleted	37	18	666
Total	87	.....	7,196

The dense areas are close to the shoal spots, and in various places bear from 101 to 178 bushels per acre, the average density being sufficient to yield about 22 bushels per day to the tonger.

The bottom of very scattering growth covers but a small spot at the outer end of the middle shoal, and the density of growth is sufficient to yield barely 5 bushels of seed oysters per day.

The depleted bottom is practically denuded. It bears very few shells, and the very scattering bottom is little better in this respect, but the shell deposit on the dense areas is good.

DETAILS OF EXAMINATION OF BEDS BETWEEN ROCK WHARF SHOALS AND SPINDLE ROCK.

SPINDLE ROCK.

This bed follows the line of a shoal at right angles to the shores. It consists principally of a dense growth, with insignificant areas of very scattering oysters and depleted bottom at its inner end. Its area and condition at the time of the survey were as follows:

OYSTER GROWTH ON SPINDLE ROCK.

Character of growth.	Area.	Oysters per acre.	Estimated total content of oysters.
	Acres.	*Bushels.*	*Bushels.*
Dense	14	140	1,960
Very scattering	3	27	81
Depleted	2	12	24
Total	19		2,065

The dense area bears a growth of between 119 and 179 bushels per acre, and is capable of producing about 21 bushels of oysters per day's tonging; the area of very scattering growth will yield barely 5 bushels and the depleted bottom about 2 bushels. The area of dense growth bears a good supply of shells, that of very scattering growth hardly enough to insure reseeding except under the best conditions, while the depleted bottom is deficient.

The following examinations were made:

PUBLIC GROUNDS.

The public oyster grounds of Virginia are those areas of the bottoms of tide water which are included within the lines of the Baylor survey and additions thereto upon which the public is permitted to take oysters at certain seasons of the year on compliance with certain conditions, and which are withheld from lease for purposes of oyster culture under private and exclusive control.

The public grounds were designed to include all of the natural rocks, though, as has been explained previously, no actual examination was made for the purpose of really determining the facts. The boundaries are necessarily straight lines and do not purport to conform to the outlines of the actual rocks, and largely for this reason they can not fail to include within their confines more or less barren bottom. The relation which the barren bottoms bear to that which actually produces oysters has been in more or less acrimonious dispute between the tongers and dredgers on the one hand and the planters and their partisans on the other, and it was largely to secure authentic and definite information on this point that the present survey was undertaken.

The public grounds are officially designated by numbers and the name of the county within which they are supposed to lie, and on the accompanying charts their boundaries, accurately platted from the charts of the Baylor survey, are indicated by broken black lines. The boundaries of the natural rocks, as determined by the present survey, are shown in solid red lines, within which the varying density of oyster growth is shown by the relative density of the shading. An inspection of the charts will show that the natural rocks are more or less scattered, between and about them lying barren bottoms, shown as unshaded areas, within the boundaries of the Baylor survey.

At various places it was found that certain private grounds, as indicated by the boundary stakes, encroached more or less on the public grounds, though from the flimsy character of the marks it was difficult in many cases to determine the real facts. This apparent encroachment of private interests on the public domain was observed at various places in Nansemond River, between Fishing Point and Ballards Marsh, about Creek Channel Shoal and Aaron Shoal rocks, in the vicinity of Browns Shoal rocks, at the inshore edges of Kettle Hole and Blunt Point rocks, and at various places between Jail Island and Mulberry Point.

Whatever may have been the conditions under which this encroachment was originally permitted, it was undoubtedly aided by the latter-day uncertainty as to the Baylor boundaries. Apparently but little effort has been made to maintain or replace the shore marks to which the corners of the Baylor survey were referred, and a number of them appear to be now unavailable for reference. The irregularity of the boundaries has also made the maintenance of the lines more difficult, and the same conditions have made it almost impossible for the oyster police to prevent the planters from depredating the public beds beyond their staked boundaries.

These reasons have made it important to both "natural growthers" and planters that an examination should be made into the actual location of the productive areas or those which, though at present more or less unproductive, may be reasonably expected to recuperate under proper natural conditions.

To assist to an understanding of the conditions on the public beds as a whole the following discussion is offered. The several public beds in the region surveyed are considered with regard to the relative areas of dense, scattered, very scattered, and depleted growths, and barren bottom. The first four are measured from the results of the present survey, while the barren bottom is regarded as the difference between the sum of these areas and the areas of the public beds according to Baylor's computations, the data being exhibited in tabular form for each of the several public grounds. For each public ground or for each fraction or combination considered as an entity in the following pages, there are furnished tables and

summaries of the estimated total contents of market oysters, as distributed by rocks and varying densities of growth. These estimates are interesting, but are misleading if regarded as a measure of productiveness, for a very sparse growth over a large area, as compared with a dense growth over a small one, will give a great aggregate which really represents nothing commercially, as the oysters may be so thinly scattered as to be totally unavailable industrially.

The important point is not how many oysters there may be on a given bed at a given time, but the quantity of oysters available under existing local economic conditions, the maximum number of bushels that can be removed with profit to the tonger.

It is unnecessary to explain to those familiar with the oyster industry that it is practically impossible to accomplish a complete denudation of the beds in any one season, but there are cases known to the writer, though he has no personal knowledge of the kind in the region under discussion, in which small rocks have been, in effect, taken up bodily, oysters, seed, and shells, and transferred to planted beds.

Under ordinary circumstances, in localities where the cull laws can be and are reasonably enforced, not only the seed or young oysters but a considerable proportion of the market oysters are left on the beds at the end of the season. Eventually, however, the oysters become so scattered that the daily yield to the tonger becomes less than a minimum daily wage, and while the aggregate quantity of marketable oysters left on the beds appears large when expressed in a total of bushels, as in the tables of total contents, it will no longer pay to take them. The minimum average density of growth to which a bed may be reduced before becoming commercially unproductive depends primarily upon the price of oysters. The smaller the market value of a bushel of oysters the greater is the quantity that must be taken per day to furnish a living wage. Another factor that is essentially involved is the amount of culling required, less labor being necessary in handling the oysters when they are single or in small clusters than when they are badly clustered and overgrown with young, from which they must be separated before being placed on the market.

The depth of water is also a very important factor in determining the actual density of growth necessary to render a bed commercially productive. As has been explained in describing the methods pursued in the preparation of this report, the deeper the water the greater must be the quantity of oysters per square yard or acre necessary to afford the tonger a given catch per day. Not only do his tongs of any given length of shaft and head cover a smaller area on the bottom, but the time and labor of making the "grab"—that is, putting the tongs on the bottom, scraping up the oysters, and pulling them up—are materially increased. In other words, in deep water

not only is the area covered by a "grab" smaller, but, other things being equal, fewer "grabs" can be made in an hour than in a smaller depth.

In the tables shown in this report and on the chart these factors have all been considered in estimating the relative density of the beds. In the estimation of the available contents of the rocks as exhibited in the following tables the same factors have been considered. It is assumed that, at the price which has recently been received for market oysters in the region under consideration—namely, 45 cents per bushel—it would be wholly unprofitable to tong on bottoms which would yield less than 3 bushels of culled oysters per day, exclusive of the time spent in culling, which would ordinarily involve part of the time of a second man or boy. In the same way at the price of seed oysters, namely 30 cents per bushel, it is assumed to be equally unprofitable to tong on bottoms yielding less than 4 bushels, exclusive of shells.

It can not be argued that this limit is too high, but undoubtedly it will be claimed by some that it is entirely too low. The objection would be well founded if it were to apply wholly to areas on which the initial density of growth was such as to afford the minimum yield adopted, but it will not lie against the application of the standard to areas of greater initial productiveness. A dense bed in course of partial denudation by tonging is not uniformly depleted over its whole area. The tongers spread themselves more or less promiscuously over the rocks and take up practically all of the oysters in patches, while other areas are, for the time being, inadvertently left untouched. Later many of these untouched spots are tonged with profit, until the worked areas become so great in proportion to those which have been overlooked that the time spent in searching for the latter makes further work unremunerative. At this stage of temporary abandonment the rock consists of a few small patches of productive bottom, areas which are practically bare of market oysters, and others which have been worked over but still retain some oysters scattered over them by the operations of tonging. It is of course impossible, from the complexity and irregularity of the conditions obtaining on an oyster bed, to fix a limit of more than reasonable accuracy. In preparing the following tables the present available productiveness of each area has been considered with regard to the terms of its initial yield to the tonger and its total estimated contents above that which would give a return of 3 bushels per day's work on the market oyster beds and 4 bushels on the seed beds. The depleted areas and most of the areas covered by what is called very scattered growth are therefore negligible as present factors. A very few areas in the depleted bottoms and a somewhat greater proportion of the bottoms bearing a very scattering growth are of potential value as bearing small oysters and shells which reasonably assure future regeneration.

These are pointed out in the following discussion of the several public grounds:

PUBLIC GROUNDS NO. 2 NANSEMOND COUNTY AND NO. 6 ISLE OF WIGHT COUNTY.

These two grounds overlap, as platted on the state charts, and as they can not be accurately differentiated in the conflicting area they may be most conveniently considered together. The former bed begins at the upper limit of oyster growth in the Nansemond River off Cedar Point, and becoming continuous with No. 6 near Newport News Rock, the latter extends along the right side of the James River to beyond Ballards Marsh Rock. Ground No. 2 is said to contain 3,319.6 acres, and Ground No. 6, 4,148.2 acres, a total of 7,467.8; but there is an overlap or duplication of about 305 acres, and deducting this, the actual total area of the two beds may be assumed to be about 7,162.8 acres. The following is a résumé of the extent of the oyster bottoms of the several rocks and the barren bottom embraced within the limits of these grounds:

AREAS OF OYSTER GROWTH IN PUBLIC GROUNDS NO. 2 NANSEMOND COUNTY AND NO. 6 ISLE OF WIGHT COUNTY.

Name of oyster rock.	Oyster growth.				
	Dense.	Scattering.	Very scattering.	Depleted.	Total.
	Acres.	*Acres.*	*Acres.*	*Acres.*	*Acres.*
Larkins	0	0	0	39	39
Nansemond Ridge	85	446	294	782	1,607
Drum Shoal	0	19	14	95	128
Newport News	4	27	12	129	172
Cruiser Shoal	27	19	26	32	104
Between Nansemond Ridge and Fishing Point [a]	50	0	5	7	62

Ballards Marsh	0	4	33	142	179
Total oyster area	256	641	512	1,639	3,048
Total barren bottom					4,114.8
Total Baylor survey					7,162.8

[a] 8 acres undetermined.

It will be observed from this table that the barren bottom, as developed by this survey, exceeds the area of the oyster rocks and constitutes about 57 per cent of the area of the two public grounds under discussion. The depleted bottom, which, excepting the places noted in the detailed descriptions of the several beds, is at present unproductive and of a character that gives little or no promise of future regeneration, forms about 23 per cent of the total area included within the Baylor lines. Assuming that the areas of very scattering

growth, at present practically worthless so far as actual productiveness is concerned, are capable of coming into production at some time in the future, by virtue of the young growth and clean shells that they bear, it will be seen that the actual productive oyster rocks form only about 20 per cent of the area of these two public grounds.

The estimated total marketable contents of the grounds, based upon the distribution of oysters, as indicated by the chain, and the actual productiveness of the various areas as determined by actual count and measurement, is exhibited in the following table:

CONTENT OF MARKET OYSTERS, PUBLIC GROUNDS NO. 2 NANSEMOND COUNTY AND NO. 6 ISLE OF WIGHT COUNTY.

Name of rock.	Dense.	Scattering.	Very scattering.	Depleted.	Total.
	Bushels.	*Bushels.*	*Bushels.*	*Bushels.*	*Bushels.*

Ballards Marsh		124	792	894	1,810
Total	28,468	39,087	17,855	21,052	106,462

This indicates that if it were possible to "clean up" completely the entire area covered by the oyster rocks, the product would be about 106,000 bushels of marketable oysters. When an analysis is made, it is speedily apparent that the commercially available supply on these beds is only about 40 per cent of the foregoing, as stated in the following table:

AVAILABLE CONTENT OF MARKET OYSTERS, PUBLIC GROUNDS NO. 2 NANSEMOND COUNTY AND NO. 6 ISLE OF WIGHT COUNTY.

Name of rock.	Dense.	Scattering.	Very scattering.	Total.

Total	21,150	20,325	1,600	43,075

It will be observed that on the basis assumed in this report the depleted areas are wholly unproductive commercially, and the bottoms covered with very scattered growth are practically so. On the latter the growth in many cases is barely sufficient to yield 3 bushels per day, and in no case does it much exceed that limit. The large aggregate of market oysters on the areas of very scattered and depleted bottoms are so thinly distributed as to be unavailable commercially, and are therefore valueless except as brood stock to assist in furnishing spat for replenishing the beds. On the dense areas about three-fourths of the total contents and on the scattering growths about one-half may be taken with profit.

The total estimated available product of 43,075 bushels appears very small as compared with the area included within the Baylor lines, averaging but about 6 bushels per acre. It is about half of the average yield of marketable oysters on the public grounds of the State as a whole in 1901 and 1904, according to the statistics of the Bureau of Fisheries, and about equal to the average yield in 1908, as stated by the Bureau of the Census.

The deficiency in productiveness of this section was to be expected in view of public report. The beds, especially in Nansemond River, are generally recognized as being seriously depleted, the allegation of the tongers being that several years ago large quantities of unculled stock were taken from the beds for deposit on private planting ground, and the tonger employed by the survey is authority for the statement that the growth on the Nansemond River beds in the season preceding the investigation was hardly sufficient to warrant tonging.

Combining the exhibits of the tables of areas and of commercially available oysters, we find that it apparently would be profitable to take from the dense growths about 83 bushels per acre and from the scattering growths an average of about 32 bushels. On the bottoms with a very scattering growth the average content per acre at the beginning of the present oyster season was so small that, even under the very low standard of profit adopted in this report, the beds would be reduced to unproductiveness after an average of only about 3 bushels of oysters per acre had been removed. Of course a very large part of this bottom must be regarded as practically unproductive in the beginning, and it is only here and there that even the least ambitious tonger would venture to work.

Another aspect of the present state of these grounds is the production of young oysters and the presence of shells in such quantities and cleanliness as to afford prospect of a strike under proper conditions. The following table gives the estimated total content of the several rocks and of the grounds as a whole in oysters less than 3 inches long:

TOTAL CONTENT OF YOUNG OR SEED OYSTERS, PUBLIC GROUNDS NO. 2 NANSEMOND COUNTY AND NO. 6 ISLE OF WIGHT COUNTY.

Total	31,818	86,050	26,854	57,038	201,760

In individuals the small oysters are five or six times as numerous as the market oysters and in measured quantity they are about twice as abundant. On the dense areas they bulk about the same as the market oysters, but as individuals they are two or three times as many. On the scattered area they much exceed the market oysters in numbers and are more than double them in measured quantity. As both of these types of bottom are almost invariably supplied with cultch in the form of clean shells, it can be safely assumed that their future is assured under ordinarily fair conditions and provided the beds are not stripped under infractions of the culling law.

On the area of very scattering growth the quantity of young in nearly every case materially exceeds that of market oysters. Almost the sole exception is Nansemond Ridge Rock, where the young and market oysters are about equal in quantity, the former being decidedly deficient in all places excepting close to the denser areas below a line between Pig and Barrel Points.

Excepting Nansemond Ridge Rock the very scattering areas bear an average of about two and one-half times as many bushels of young as of old oysters per acre, and there is nearly everywhere a sufficient abundance of shells to justify the prediction of future regeneration if man will permit. On Nansemond Ridge the future of the very scattering areas, except in a few places, appears unpromising.

The depleted area is, on the whole, deficient in shells and young oysters, and if we except one or two spots near Nansemond Light, the outer end of Ballards Marsh Rock, and several other places quite close to the productive areas, there is but little probability that any of the area will become naturally productive.

PUBLIC GROUND NO. 1 WARWICK COUNTY, BELOW DEEP CREEK.

This public ground, while continuous in its lines from near Newport News to above Deepwater Shoals Light, is divided, for purposes of administration, by a line running from Deep Creek to Days Point. Below this line the cull law is in force and tonging is practically confined to taking oysters for the market, while above the line it is legally permissible to take oysters of all sizes for planting purposes. The total area of the portion of the bed here discussed is about 5,515 acres. It embraces six well-defined rocks or groups of rocks, the general condition and area of which are shown in the following table, which also includes a very small contiguous and overlapping area at the inshore edge of Kettle Hole Rock, known as Public Ground No. 2 Warwick County:

AREAS OF OYSTER GROWTH, PUBLIC GROUND NO. 1 WARWICK COUNTY, BELOW DEEP CREEK.

Name of oyster rock.	Dense.	Scattering.	Very scattering.	Depleted.	Total.
	Acres.	*Acres.*	*Acres.*	*Acres.*	*Acres.*
Browns Shoal	68	44	27	226	365
Gun Shoal	6	0	16	4	26
Kettle Hole	258	66	111	11	446
Thomas Point	76	118	100	127	421
Blunt Point	16	69	225	118	428
White Shoal	44	0	10	52	106
Total oyster area	468	297	489	538	1,792
Total barren bottom					3,723
Total Baylor survey					5,515

As shown above, the barren bottom is equal to about 68 per cent of the area included within the Baylor lines, while the depleted area, which is almost uniformly worthless in its present condition, is equal to about 10 per cent. Assuming, as has been done in the discussion of the preceding grounds, that the bottom bearing a very scattering growth, of little or no present value so far as its market-oyster content is concerned, is capable of regeneration under the operation of natural agencies, the total present or prospective productive bottom constitutes about 22 per cent of the entire area. The following table shows the estimated present market-oyster content of the several rocks and their respective subdivisions according to density of growth:

CONTENT OF MARKET OYSTERS, PUBLIC GROUND NO. 1 WARWICK COUNTY, BELOW DEEP CREEK.

Name of rock.	Dense.	Scattering.	Very scattering.	Depleted.	Total.
	Bushels.	*Bushels.*	*Bushels.*	*Bushels.*	*Bushels.*
Browns Shoal	12,444	2,376	1,053	904	16,777
Gun	912		480		1,392
Kettle Hole	27,090	5,412	4,662		37,164
Thomas Point	8,745	8,378	5,100	2,667	24,890
Blunt Point	2,576	4,140	10,125	1,652	18,493
White Shoal	5,588		360	624	6,572
Total	57,355	20,306	21,780	5,847	105,288

The total content is nearly equal to that of the two grounds first described, but it will be observed that it is differently distributed, the dense areas bearing about twice the quantity of marketable oysters, the scattering about half as many, the very scattering about one-third more, and the depleted about three-fourths the quantity. With the exception of the depleted bottom, the average growth per acre is in each case somewhat greater than upon the grounds on the opposite side of the James and in the Nansemond River.

As will be understood from what has gone before, this distribution of the total content is to the distinct advantage of the oysterman, as a larger proportion of the oysters may be removed before work on the beds becomes unremunerative. The estimated available content of the beds embraced within this part of the public grounds—that is, the probable maximum yield during the present season—is shown in the following table:

AVAILABLE CONTENT OF MARKET OYSTERS, PUBLIC GROUND NO. 1 WARWICK COUNTY, BELOW DEEP CREEK.

Name of rock.	Dense.	Scattering.	Very scattering.	Total.
	Bushels.	*Bushels.*	*Bushels.*	*Bushels.*
Browns Shoal	9,800	1,200	250	11,250
Gun	600			600
Kettle Hole	18,900	2,700	800	22,400
Thomas Point	6,000	4,200	500	10,700
Blunt Point	2,000	2,000	2,000	6,000
White Shoal	4,000			4,000
Total	41,300	10,100	3,550	54,950

Practically four-fifths of the available oysters are found on the areas charted as bearing a dense growth, and about two-thirds of the remainder are on the areas of scattering growth. The bottoms covered by oysters in very scattering growths are slightly more productive than the average of the grounds previously described, but there are comparatively few spots on which a tonger could make a minimum livelihood. It is estimated that on the dense areas as a whole nearly three-fourths of the total content, on the scattering areas

about one-half, and on the very scattering areas not over one-sixth could be removed with profit. The depleted bottoms are worthless for their present product of market oysters.

The yield per acre of bottom included within the Baylor lines is considerably greater than on the grounds previously described, the average being almost 10 bushels, 2 bushels less than the average of the entire public area of Virginia in 1904, and considerably more than the average reported by the Census Bureau in 1908. The average available product of the oyster rocks, excluding all barren bottom but not that which it depleted, is about 30 bushels per acre. The average of the dense area is about 88 bushels, of the scattering area 34 bushels, and of the very scattering growth about 7 bushels per acre. The rocks in this ground are, on the whole, so far as present productiveness is concerned, in better condition than those across the river. The probable future productiveness of the beds, so far as the present existence of young oysters is concerned, is illustrated in the following table:

TOTAL CONTENT OF YOUNG OR SEED OYSTERS, PUBLIC GROUND NO. 1 WARWICK COUNTY, BELOW DEEP CREEK.

Name of rock.	Dense.	Scattering.	Very scattering.	Depleted.	Total.
	Bushels.	*Bushels.*	*Bushels.*	*Bushels.*	*Bushels.*
Browns Shoal	8,568	6,248	2,376	1,130	18,322
Gun	1,188	.....	992	.....	2,180
Kettle Hole	81,786	13,662	19,980	.....	115,428
Thomas Point	12,768	20,060	10,300	10,160	53,288
Blunt Point	2,736	13,317	23,625	4,956	44,634
White Shoal	14,728	.....	1,080	2,756	18,564
Total	121,774	53,287	58,353	19,002	252,416

The exhibit here is much more favorable than on the rocks included in the grounds previously described, the average growth of young oysters on the dense and very scattering areas being over double that on the beds across the river, while that on the scattering area is about 35 per cent greater.

Practically everywhere on the areas of dense and scattered growth there is a prolific growth of young oysters and an abundance of clean shells, and there is no present prospect of the failure of these areas to continue to produce marketable oysters under ordinary conditions and with a reasonable enforcement of the laws. On the areas of very scattering growth the conditions are mixed, some places being well insured against the future and others being decidedly deficient in both young growth and clean shells. On Browns Shoal Rocks there is, with the exception of a few places, an abundance of shells; but there are only two or three patches where there is a supply of small oysters ample to replace the present market growth. On Kettle Hole Rock the conditions are good practically everywhere, but on Thomas Point and

Blue Point Rocks there are but a few places where the young growth is prolific, and there are some in which neither young nor shells are found in even the minimum quantity requisite. On White Shoal Rock the condition on the areas of very scattering growth is in general satisfactory.

On the depleted bottoms as a whole the average growth of young oysters is about equal to that on similar bottom across the river, and there appears to be but little prospect of the future improvement of these areas, although there are a few spots on Thomas Point and White Shoal Rocks, in proximity to productive areas, where the growth of young is good.

MINOR PUBLIC GROUNDS.

In the Nansemond River and on the right side of James River there are several small public grounds, all of which are insignificant both in area and productiveness, and some of which were examined not at all or unsatisfactorily. They are as follows (somewhat more detailed data concerning some of them may be found in the descriptions of the individual rocks):

Nansemond County Ground No. 3. This was intended to include Holland Rock and at present contains in depleted bottom about 22 acres, on which there are a very few oysters and shells and about 33.9 acres of barren bottom.

Isle of Wight County Ground No. 2 contains about 9 acres of bottom of various degrees of productiveness, 24 acres of depleted and 16.8 acres of barren bottom. Its general condition is related in the description of Aaron Shoal Rock, its only natural bed. Isle of Wight County Ground No. 3 adjoins the preceding and has an area of 6½ acres. It was not examined in the present survey. Isle of Wight County Ground No. 4 lies inshore of the preceding and covers about 3 acres of apparently depleted bottom.

Isle of Wight County Ground No. 5 embraces Creek Channel Shoal Rock, covering about 2 acres of depleted and 5.1 acres of barren bottom. Its present condition is described under the name of the rock.

PUBLIC GROUND NO. 1 WARWICK COUNTY, ABOVE DEEP CREEK.

The lower part of this ground, lying below Deep Creek, is within the area from which market oysters only can be taken and is therefore subject to the operations of the cull law. Its beds have been discussed in the foregoing. Above Deep Creek and Days Point, on both sides of the river, the cull law is suspended so far as young oysters are concerned, and, while shells must be returned to the beds, there is no limit on the minimum size of oysters which may be taken, the whole area being set apart for the production of seed for replanting.

It is necessary, therefore, in the discussion of the productiveness of this part of the James River oyster grounds, to adopt a different standard of productiveness. The whole oyster product of whatever size is involved in the question of the present value of the beds, whereas in the areas previously discussed the market oysters only could be considered, and the quantity of young was of interest merely as indicating the probability of the beds being maintained or repleted. In the discussion which follows here the maximum potential yield is considered as the production in excess of that which will give the tonger 4 bushels of oysters per day of tonging, not taking into consideration the time employed in culling out the shells and returning them to the beds.

This part of Ground No. 1 includes all oyster rocks on the left bank of the James River, from the mouth of Warwick River to the upper limit of oyster growth, near Deepwater Shoals Light-House. The following is a summary of the extent of the several rocks and the barren bottoms embraced within the Baylor lines:

AREAS OF OYSTER GROWTH, PUBLIC GROUND NO. 1 WARWICK COUNTY, ABOVE DEEP CREEK.

Name of rock.	Dense.	Scattering.	Very scattering.	Depleted.	Total.
	Acres.	*Acres.*	*Acres.*	*Acres.*	*Acres.*
Jail Island	227	198	14	508	947
Wreck Shoal	586	0	0	0	586
Dry Shoals	126	18	9	21	174
Point of Shoals	254	155	239	142	790
Swash	146	0	0	115	261
Mulberry Swash	422	34	20	29	505
Marshy Island	197	322	235	387	1,141
Long Shoal	331	10	84	79	504
V Rock	240	0	73	73	386
Moores	37	6	0	0	43
Horsehead	33	192	139	16	380
Deepwater Shoals	17	0	21	241	279
Total oyster area	2,616	935	834	1,611	5,996
Total barren area					6,896.8
Total Baylor survey					12,892.8

It will be noticed at once that the proportion of barren bottom to that actually included in the rocks as determined by the survey is somewhat smaller than in the grounds previously discussed, constituting about 53 per cent of the total. The depleted bottom, which, with practically no exceptions, is at present and potentially valueless, covers an additional 12 or 13 per cent, so that, assuming all the rest to be at present productive or capable of becoming so in the future, the oyster bottom covers about 35 per cent of the whole.

The following table exhibits the estimated total content of the several rocks and their subdivisions at the opening of the oyster season on September 15, 1909:

TOTAL CONTENT OF OYSTERS, PUBLIC GROUND NO 1 WARWICK COUNTY, ABOVE DEEP CREEK.

Name of rock	Dense.	Scattering.	Very scattering.	Depleted.	Total.
	Bushels.	*Bushels.*	*Bushels.*	*Bushels.*	*Bushels.*
Jail Island	32,461	21,582	392	4,064	58,499
Wreck Shoal	185,176				185,176
Dry Shoals	30,766	2,232	765	420	34,183
Point of Shoals	50,800	14,415	10,038	2,130	77,383
Swash	42,778			1,725	44,503
Mulberry Swash	127,444	3,604	2,600	1,247	134,895
Marshy Island	45,507	41,538	19,975	6,966	113,986
Long Shoal	79,771	640	5,040	1,264	86,715
V Rock	54,480		6,132	1,095	61,707
Moores	9,805	1,008			10,813
Horsehead	7,359	19,968	15,568		42,895
Deepwater Shoals	2,193		1,097	2,892	6,182
Total	668,540	104,987	61,607	21,803	856,937

It will be seen that the great preponderance of oyster production is on the dense areas, which exceed the bottoms of other character not only in their average productiveness but in their total area. The bottoms with a scattering growth, which in extent exceed the next lower grade by about 12 per cent, excel them in their total content by about 70 per cent, and are considerably more important in total production than the combined areas of very scattering oysters and depletion. Summarizing, the dense areas bear 78 per cent of the total content of the rocks, the scattering areas about 12 per cent, the very scattering about 7 per cent, and the depleted bottom about 3 per cent. Basing the computation on the basis previously defined and the data presented in the preceding two tables, we find the estimated maximum available product of the several rocks and their subdivisions to be as follows:

AVAILABLE CONTENT OF OYSTERS, PUBLIC GROUND NO. 1 WARWICK COUNTY, ABOVE DEEP CREEK.

Name of rock.	Dense.	Scattering.	Very scattering.	Total.
	Bushels.	*Bushels.*	*Bushels.*	*Bushels.*
Jail Island	25,000	12,000	100	37,100
Wreck Shoal	160,000			160,000
Dry Shoals	26,000	1,300		27,300
Point of Shoals	42,000	8,500	1,000	51,500
Swash	38,000			38,000
Mulberry Swash	116,000	1,800	1,000	118,800
Marshy Island	35,000	25,000	7,500	67,500
Long Shoal	68,000	300	1,500	69,800
V Rock	44,000		2,500	46,500
Moores	7,500		500	8,000
Horsehead	6,000	11,000	7,000	24,000
Deepwater Shoal	1,600		400	2,000
Total	569,100	59,900	21,500	650,500

The foregoing may be assumed to be the maximum quantity of seed oysters that can be profitably taken from the beds during the present season and the actual yield will probably fall considerably below the total exhibited in the table. Of the total, the areas of dense growth are capable of producing 88 per cent, of scattering growth 9 per cent, and of very scattering growth 3 per cent. The estimated yield per acre of bottom included within the boundary lines of this part of the bed is about 50 bushels. This low average of production is of course induced by the large area of barren and depleted or practically barren bottom included in the Baylor lines. If we compare the average of the whole area with that of the best bottom in the natural rocks under discussion the paucity of the former is equally impressive, the dense areas of the region under discussion having an average total content of about 256 bushels per acre and a promised yield during the present season of 213 bushels, over four times the average of the beds as a whole. The average available product of the areas of scattering growth is about 64 bushels per acre, and of very scattering growth about 13 bushels, both yields being far below what they should produce under proper conditions.

Upon the dense areas as a whole the present production and the promise for the future are both good, and on the area of scattering growth, while the present production is fair, the quantity of shells is such as to promise a better yield in the future, should there come a season of heavy and general strike.

On the bottoms rated as bearing a very scattering growth the conditions as a whole are not such as to yield much profit to the tonger, though in some places he could make a living wage for a short period. In most places on bottom of this character the quantity of clean shells is such as to give indifferent prospect of the future regeneration of the beds.

The depleted bottom, excepting in a few places near Deepwater Shoals Light-House, bears shells in such small quantities as to make exceedingly remote the probability of any material improvement under natural conditions.

PUBLIC GROUND NO. 1 ISLE OF WIGHT COUNTY.

This ground extends as a narrow strip along the right bank of James River from close to the shore line out to the main channel, between Rock Wharf and Days Point Shoal. It lies wholly within the area set apart for seed production, and the statements in regard to the methods employed in computing the productiveness of the several parts of the preceding ground are applicable to this as well.

Compared with the extensive areas occupied by the rocks across the river in Warwick County, the beds included in this ground are

insignificant. For the purposes of this report it is considered to include four natural rocks, although the largest of these, for which no name was obtained from the oystermen, may be locally recognized by names for its constituents severally. The general condition and extent of the bed are shown in the following table:

AREAS OF OYSTER GROWTH, PUBLIC GROUND NO. 1 ISLE OF WIGHT COUNTY.

Name of oyster rock.	Dense.	Scattering.	Very scattering.	Depleted.	Total.
	Acres.	*Acres.*	*Acres.*	*Acres.*	*Acres.*
Rock Wharf Shoals	18	0	0	8	26
Between Rock Wharf and Spindle Rock	45	0	5	37	87
Spindle	14	0	3	2	19
Days Point Shoal	4	0	0	0	4
Total oyster area	81	0	8	47	136
Total barren area					589
Total Baylor survey					725

The area of barren bottom as compared with the extent of the ground is relatively large, constituting about 81 per cent, and the depleted bottom, which is at present worthless and holds forth no promise of improvement, adds an additional 7 per cent to the wholly unproductive bottom. The area of dense growth, which is undoubtedly productive, covers about 11 per cent of the whole, while the bottom bearing very scattered oysters, which is at present practically incapable of yielding a living wage to the tonger, covers about 1 per cent.

The following table shows the estimated total content of oysters on the rocks at the end of August, 1909:

TOTAL CONTENT OF OYSTERS, PUBLIC GROUND NO. 1 ISLE OF WIGHT COUNTY.

Name of rock.	Dense.	Scattering.	Very scattering.	Depleted.	Total.
	Bushels.	*Bushels.*	*Bushels.*	*Bushels.*	*Bushels.*
Rock Wharf Shoals	2,520			88	2,608
Between Rock Wharf Shoals and Spindle Rocks	6,300		230	666	7,196
Spindle	1,960		81	24	2,065
Days Point Shoal	664				664
Total	11,444		311	778	12,533

The total content of the ground as a whole averages about 17 bushels per acre. Practically all of this is borne by the small fraction of the bottom classed as dense, on which the average production is at the rate of about 141 bushels per acre, considerably less than on the areas of dense growth on the great beds across the channel.

The estimated available content on these beds—that is, the quantity which may be removed before tonging will cease to pay even a very small assumed minimum livelihood—is as follows:

AVAILABLE CONTENT OF OYSTERS, PUBLIC GROUND NO. 1 ISLE OF WIGHT COUNTY.

Name of rock.	Dense.	Scattering.	Very scattering.	Total.
	Bushels.	*Bushels.*	*Bushels.*	*Bushels.*
Rock Wharf Shoals	2,000	.....	.....	2,000
Between Rock Wharf Shoals and Spindle Rock	5,000	.....	50	5,050
Spindle	1,500	.....	20	1,520
Days Point	500	.....	.....	500
Total	9,000	.....	70	9,070

Practically all of the available supply of oysters on this ground is therefore on the bottom classed as dense and the area of very scattering growth is negligible. The available product is of the average density of 111 bushels per acre. On the dense area the shells are sufficient, on the very scattering area they are in fair quantity, while on the depleted ground they are deficient.

SUMMARY.

The public grounds in the region covered by the survey and of which a detailed discussion is found in the preceding pages cover an area of 26,408.4 acres as computed in the report of the Baylor survey. Of this acreage, 12,790.6 acres lie below the line drawn between Deep Creek and Days Point and 13,617.8 acres lie above that line. The beds of the former region are available for the production of marketable oysters only, the law requiring that all oysters under 3 inches long be returned to the beds, while the latter region is set apart for the production of seed oysters, and the cull law is not applicable except in so far as it forbids the removal of shells.

Of the entire area the recent survey shows that 3,227 acres may be classed as bearing a dense growth, 2,078 as scattering, 1,848 as very scattering, 3,884 as depleted, and 15,371.4 as barren. The barren and depleted bottoms together comprise 19,255.4 acres, or about 73 per cent of the total, and all bottom which can be construed as productive aggregates 7,153 acres, or 27 per cent of the entire bottom included within the Baylor lines. Owing to the difference in the provisions of the law applicable to the two regions and the resultant difference in the character of their product, it is necessary to present separate summaries of their present condition.

MARKET OYSTER AREA.

The beds of this region are shown on chart 1 accompanying this report, to which, and to the preceding pages, readers are referred

for detailed data. The following table summarizes the extent and character of the bottom included within the Baylor lines:

SUMMARIZED STATEMENT OF MARKET OYSTER AREAS ON PUBLIC GROUNDS.

Name of ground.	Dense.	Scattering.	Very scattering.	Depleted.	Barren.	Total.
	Acres.	*Acres.*	*Acres.*	*Acres.*	*Acres.*	*Acres.*

Per cent	5.7	7.4	7.9	17.4	61.6	100.0

It is estimated that the bottoms embraced by the several grounds, classified in accordance with their relative productiveness, have a total content of market oysters as follows:

SUMMARIZED CONTENT OF MARKET OYSTERS ON PUBLIC GROUNDS.

Name of ground.	Dense.	Scattering.	Very scattering.	Depleted.	Total.
	Bushels.	*Bushels.*	*Bushels.*	*Bushels.*	*Bushels.*

Isle of Wight No. 4					
Isle of Wight No. 5				22	22
Warwick No. 1 and No. 2 (below Deep Creek)	57,355	20,306	21,780	5,847	105,288
Total market oysters	86,023	59,525	39,704	27,383	212,635
Average per acre	118	63	39	12	
Per cent of total	40.3	28.0	18.7	13.0	100

This table is more or less misleading, as the real factor involved is the quantity of oysters which can be profitably removed from the beds. It must be obvious that the total quantity lying on the bottom can not be regarded as commercially available, for when the density of growth is reduced below a more or less definite minimum the value of the average catch will fall below a minimum living wage and work will cease. The minimum average quantity per unit of bottom which will suffice to support commercial operations will depend upon the price of oysters and the depth of water. In this report the price is placed at 45 cents per bushel, and although it will vary somewhat on the different beds and at different times, it is not practicable to make distinctions. The price adopted is based on the testimony of a number of oystermen as to their returns in recent years. The depth of water is a highly variable factor, and as it is of prime importance in

computing the availability of the oysters lying on the bottom, its variations have been given the fullest possible consideration. For a discussion of the general principles on which the quantity of oysters available with profit have been determined, the reader is referred to preceding pages. For the market oyster beds as a whole the following table gives a summary:

SUMMARY OF AVAILABLE CONTENT OF MARKET OYSTERS ON PUBLIC GROUNDS.

Name of ground.	Dense.	Scattering.	Very scattering.	Total.
	Bushels.	*Bushels.*	*Bushels.*	*Bushels.*
Nansemond No. 2	21,150	20,325	1,600	43,075
Isle of Wight No. 6				
Nansemond No. 3				
Isle of Wight No. 2	150	50		200
Isle of Wight No. 3				
Isle of Wight No. 4				
Isle of Wight No. 5				
Warwick No. 1 and No. 2 (below Deep Creek)	41,300	10,100	3,550	54,950
Total available market oysters	62,600	30,475	5,150	98,225
Average per acre	86	32	5	
Per cent	63.7	31.0	5.3	100.0

This may be regarded as a maximum estimate of the probable yield of the beds during the season of 1909–10. Owing to the low basis adopted as a minimum wage the yield may not reach the quantity indicated, as it is doubtful whether the beds can be profitably fished as closely as has been assumed. A yield of $1.35 per full day of tonging will leave a very small balance after culling and other expenses are deducted, and the beds undoubtedly will be abandoned for the season before this degree of depletion has been reached. For this reason the only parts of the natural rock which can be classed as really productive are those designated as dense and scattering, which furnish, according to the foregoing estimates, about 95 per cent of the available product while constituting only about 13 per cent of the total area of the public grounds under consideration.

Taken as a whole, though there are exceptions noted in the preceding accounts of the individual rocks, the areas covered with very scattering growths are of but little present value, their total estimated available product during the present season being valued at less than $2,500, or about $2.50 per acre. There is, however, another phase to the question which has been touched on in the more detailed accounts of the individual rocks. This is the possibility of future improvement, and is dependent upon the existing quantity of young oysters and the presence of an ample supply of clean shells to serve as places of attachment for future generations of young. The quantity of young oysters less than 3 inches long on the public grounds under discussion at the opening of the present oyster season was as follows:

SUMMARIZED CONTENT OF YOUNG OYSTERS ON PUBLIC GROUNDS.

Name of ground.	Dense.	Scattering.	Very scattering.	Depleted.	Total.
	Bushels.	*Bushels.*	*Bushels.*	*Bushels.*	*Bushels.*
Nansemond No. 2	31,818	86,050	26,854	57,038	201,760
Isle of Wight No. 6					
Nansemond No. 3				50	50
Isle of Wight No. 2	250	500		2,500	3,250
Isle of Wight No. 3					
Isle of Wight No. 4					
Isle of Wight No. 5					
Isle of Wight No. 6					
Warwick No. 1 and No. 2 (below Deep Creek)	121,774	53,287	58,353	19,002	252,416
Total	153,842	139,837	85,207	78,590	457,476
Average per acre	212	148	84	35	
Per cent	33.7	30.6	18.6	17.1	100.0

Here again is evidence that the areas of dense and scattering growth should be regarded as not only at present but prospectively productive beds. In quantity, and to a greater extent numerically, the young are considerably in excess of the market oysters, and, as in both classes of bottom under consideration the latter are sufficient to render the bottom undoubtedly at present productive, the abundance of young is sufficient to continue productiveness, under proper regulations as to culling, for at least two years. After the lapse of that period the condition will depend upon the extent of the strike, and other factors concerning which nothing can be predicted.

So far as the areas covered with a very scattering growth are concerned closer scrutiny is required. As these bottoms are on the verge of depletion in respect to market oysters, the proportion of young to large oysters should be greater to insure that the conditions will improve in the future.

The writer is not in possession of definite experimental data applicable specifically to the James River, but from a knowledge of conditions in other parts of the Chesapeake region he feels justified in assuming that oysters as an average will become fit for market in from two to three years from the time of fixation or setting. If experience elsewhere be a guide, some oysters will grow more rapidly and some less rapidly; but two years may be adopted, with very little question, as an irreducible minimum for the average age at which they can be advantageously put on the market. On this assumption and neglecting, for the time being, the question of mortality, it is at once apparent that to maintain the present status there must be two small oysters for each market oyster killed or caught.

There is no way to determine, without long and painstaking observations, the actual average mortality at various ages on the natural rocks of James River. The experience of planters of seed oysters is valueless in this connection, being based on oysters handled and

otherwise subjected to abnormal conditions. The various locations of the natural-bed oysters and the consequently variable conditions to which they are exposed introduce a factor for which it is difficult to make allowances, and it seems impossible to do more than hazard a guess as to the proportion of young oysters now on the beds which will die before becoming marketable. It is probable that it will be somewhere between 25 and 50 per cent. Considering the size of young oysters found by the survey, the mortality may be less than the former and excepting under unfavorable conditions can hardly be greater than the latter. Assuming that 25 per cent of the young now on the beds will die before reaching a marketable size, there should be on the beds, in order to maintain their present condition, 2.66 young for each marketable oyster removed. If the loss be assumed at 50 per cent there should be 4 young per market oyster.

The following table exhibits the actual average numerical proportion of young oysters to marketable found on the several beds:

NUMERICAL PROPORTION OF YOUNG GROWTH AND MARKET OYSTERS IN THE MARKET-OYSTER AREA ON BOTTOMS BEARING VERY SCATTERING GROWTH.

Name of rock.	Oysters less than 1 inch long.	Oysters between 1 and 3 inches.	Total.
Nansemond Ridge	0.42	1.82	2.24
Drum Shoal	.62	3.29	3.91
Newport News	.50	5.27	5.77
Cruiser Shoal	.55	3.83	4.38
Flat Rock, etc	.69	2.58	3.27
High Shoal	1.81	2.47	4.28
Trout Shoal	.55	6.81	7.36
Dog Shoal	.27	1.13	1.40
Fishing Point	1.11	1.94	3.05
Between Fishing Point and Ballards Marsh	.06	.00	.06
Ballards Marsh	3.50	11.40	14.90
Aaron Shoal	.66	8.00	8.66
Browns Shoal	.80	4.00	4.80
Gun	.19	4.28	4.47
Kettle Bottom	.63	8.27	8.90
Thomas Point	.21	4.06	4.27
Blunt Point	.35	4.56	4.91
White Shoal	.87	5.36	6.23
Average	.76	4.39	5.15

It will be observed that on the assumption of the smaller death rate, Nansemond Ridge, Dog Shoal, and the small beds near Ballards Marsh are the only rocks which appear to lack sufficient young growth on the very scattering areas to maintain them in their present condition. Assuming the higher rate of mortality, Drum Shoal, the small bed near Flat Rock, and Fishing Point Rocks must be added to the list, though when we consider that many of the market oysters now on the bottom can not be taken with profit, it would appear that even these rocks are capable of improving under a rigid observance of the cull law. The other rocks, under either assumption as to mortality, probably bear a sufficient number of young to

maintain their present condition or to cause slight improvement in their productiveness, and the real question at issue largely resolves itself into a matter of their present productiveness, which has been already discussed. Most of these bottoms are sufficiently clothed with shells to insure their share of a good strike. The depleted areas, excepting in the places specifically mentioned in the descriptions of the individual rocks, may be regarded as hopeless of recuperation under natural conditions.

The barren bottoms, which preceding tables show to constitute a very large proportion of the areas of the public beds, are in many cases so situated as to be of necessity and for practical considerations impossible of separation from the natural beds without injury to the future of the latter or without due regard to the question of policing and administration. There are, however, certain large areas readily separable from the public grounds, and the latter would suffer practically no diminution in really productive bottom as a result of the severance.

SEED-OYSTER AREA.

This region lies above the line drawn between Deep Creek and Days Point, and is shown on chart 2 accompanying this report. The following table summarizes the extent and condition of the bottoms of different degrees of productiveness included within this part of the Baylor survey:

SUMMARIZED STATEMENT OF OYSTER GROWTH ON SEED AREAS.

Name of ground.	Dense.	Scattering.	Very scattering.	Depleted	Barren.	Total.
	Acres.	*Acres.*	*Acres.*	*Acres.*	*Acres.*	*Acres.*
Warwick No. 1 (above Deep Creek)	2,420	1,131	834	1,611	6,896.8	12,892.8
Isle of Wight No. 1	81	0	8	47	589.0	725.0
Total	2,501	1,131	842	1,658	7,485.8	13,617.8
Per cent	18.4	8.3	6.2	12.2	54.9	100.0

The following table furnishes an estimate of the total content of seed oysters present on the bottoms of varying productiveness at the beginning of the oyster season on September 15, 1909:

SUMMARIZED CONTENT OF OYSTERS ON SEED AREAS.

Name of ground.	Dense.	Scattering.	Very scattering.	Depleted.	Total.
	Bushels.	*Bushels.*	*Bushels.*	*Bushels.*	*Bushels.*
Warwick No. 1 (above Deep Creek)	668,540	104,987	61,607	21,803	856,937
Isle of Wight No. 1	11,444	.....	311	778	12,533
Total	679,984	104,987	61,918	22,581	869,470
Average per acre	272	93	73	13	.....
Per cent	78.2	12.1	7.1	2.6	100.0

A considerable proportion of these oysters could not be profitably removed from the beds, being either too sparsely distributed in the first place or constituting a necessary remnant which would become too scattered after tonging had been carried on for a period on bottoms of greater initial productiveness. To show the estimated maximum possible yield of the beds during the present season the following table has been prepared, covering the entire area of seed beds in the James River:

SUMMARY OF AVAILABLE CONTENT OF OYSTERS ON SEED AREAS.

Name of ground.	Dense.	Scattering.	Very scattering.	Total.
	Bushels.	*Bushels.*	*Bushels.*	*Bushels.*
Warwick No. 1 (above Deep Creek)	569,100	59,900	21,500	650,500
Isle of Wight No. 1	9,000	.....	70	9,070
Total	578,100	59,900	21,570	659,570
Average per acre	232	53	25	.....
Per cent	87.7	9.1	3.2	100.0

In preparing the data on which this table is based it has been assumed that the seed will bring 30 cents per bushel and that no bottom can be considered productive when its yield is reduced below 4 bushels per day of actual tonging, excluding the time occupied in culling. As in the preceding pages of this report, the probable yield is based on the density of the oyster growth and the depth of water on the several parts of each bed.

Although the data employed differs somewhat from that used in the discussion of the bottoms below Deep Creek, owing to the lower price brought by seed as compared with market oysters, the financial return to the tonger from the bottoms designated as respectively dense, scattering, and very scattering is essentially the same. The minimum yield assumed to place a given area above the grade of depleted bottom is valued at $1.20 per day at the prices recently prevailing, and this can not be regarded as other than an extreme minimum, because, when the number of idle days is taken into consideration, a tonger could not afford to work for such low wages. The limit is justifiable only in consideration of the fact that before the dense and scattering areas are reduced to a level so low they will have yielded to the tonger an average daily wage much in excess of this.

If the price of oysters falls below 30 cents per bushel, it will not be profitable to work the beds so closely as was contemplated in the preparation of the above table. At the prices reported as current on the James River in November, 1909, namely, 20 cents per bushel for seed, the estimated catch on the area of very scattering growth may be eliminated, that on the scattering bottom reduced by at least 50 per cent and on the dense areas by about 15 per cent, lowering the

total estimated catch to about 500,000 bushels as a maximum which could be taken with profit.

As was the case with the market-oyster beds, the areas described as bearing dense and scattering growths may be dismissed from further discussion as being at present productive. The areas bearing a very scattering growth are debatable, with seed oysters selling at 30 cents per bushel, but would be undoubtedly entirely neglected by the tongers were the price to fall to 20 cents. Their estimated yield at the former price is about $7.50 per acre, and from the entire area of 842 acres the total product during the present season would not exceed in value $6,500, even if the tongers were willing to work for an average of about $1 per day, exclusive of the time lost through bad weather.

The future of these areas of very scattering growth is difficult to forecast. When, as in the area under discussion, there is not and from the nature of the case should not be any application of the cull law, there is no young growth which can be pointed to as coming forward to replace the larger oysters removed. Young and old alike are taken and the only oysters left are the residuum which it is unprofitable to take. In other words, the annual increment is taken or may be taken in the months immediately following its deposit. The health and perpetuity of the beds depend upon the quantity of clean shells exposed on the bottom ready for the strike which each season may produce. Over the very scattering bottoms of this part of James River there is a fair quantity of shells and under the proper conditions these areas may become more productive.

The depleted bottoms, as a whole, have neither present nor prospective value under natural conditions, though the bottom is generally of such character that if it were feasible to rent it for purposes of oyster culture it could be made highly productive. Much of it is so situated, however, that it is debatable whether, for reasons of administration, it would be advisable to alienate it from the public grounds. An inspection of the charts will show that, excepting along the shores, these bottoms are generally in the midst of productive areas. Concerning the great area of barren bottoms the same statement holds true in part, a considerable proportion of it lying in the channels and deeper holes between the beds or in other situations which would make it difficult to delimit it from the public grounds in a manner to facilitate the policing of the public rocks and prevent abuses which experience shows would undoubtedly be attempted.

There are, however, certain areas in considerable blocks which could be set apart for purposes of oyster culture without materially reducing the area of the natural rocks included in the public grounds. These places can be determined by an inspection of the chart.

CONCLUSION.

The foregoing gives, in detail and summary, the facts as to the condition of the oyster beds of James and Nansemond rivers immediately prior to the opening of the present oyster season, the period at which the beds are at their maximum apparent productiveness. Within a few weeks, under the intensive fishery which they sustain, the quantity of oysters on the beds will be vastly reduced and long before the close of the season they will become so impaired that work on them will be practically abandoned for the time being. In other words, it is for a part of the season only that these beds will offer a livelihood to the tongers, who for the rest of the year must seek a living either in the employ of the oyster grower or in some other occupation not connected with oyster fishing.

In the determination of the nature of tidal bottoms, with respect to their being regarded as oyster rock or barren bottom, the prime consideration is whether they will afford, either at present or prospectively, a sufficient quantity of oysters to provide a livelihood to those who work on them. It is manifest that a few oysters which could never be taken with profit should not entitle the bottom on which they lie to be regarded as an oyster bed within the meaning of the laws. To so regard them would be contrary to common sense, economic principles, and judicial decisions.

The author has avoided a definition of what constitutes a livelihood, believing that to be a matter which is more properly for determination by the state authorities should its definition become necessary for purposes of legislation or administration. In the preparation of the foregoing report, however, it has been necessary to adopt some standard for the classification of the various densities of oyster growth in the several beds, and for purposes of convenience the limit between the bottoms regarded as depleted and those of the lowest class of productiveness has been placed at a minimum believed to be reasonably irreducible. The subdivisions of productiveness differ by such small quantities that should it appear that the lowest is too low the next higher can be regarded as the minimum without impairing the value of the data adduced in the report, though, as is elsewhere indicated, this would dictate a reduction in the estimated total available product of oysters for the season.

Under the terms of the resolution of the State Board of Fisheries which was made the basis of the request for the survey preferred to the Bureau of Fisheries by the Governor of Virginia, the author is not warranted in offering recommendations as to the use which might be made of the facts developed in the preceding pages. It may not be inappropriate, however, to point out the several avenues of procedure which it is possible to follow in respect to the oyster

bottoms of the region discussed. These resolve themselves into three: (1) The maintenance of the integrity of the public grounds as now constituted; (2) their abolition in toto; and (3) a middle course which will preserve to the public the productive bottoms practically in their entirety while throwing open to oyster planting a large part of the barren and unproductive bottom now included within the public grounds. The principal arguments for and against these propositions may be epitomized as follows:

1. The first course—that the beds be retained in the present status—hardly needs discussion. It has been tried and its results are known, largely as the effect of the acrimonious disputes to which it has given rise. The matters of fact which have been at issue in these interminable discussions, as to whether or not the public grounds embraced any considerable area of barren bottom, have been dealt with in the preceding pages and speak for themselves. It should be pointed out, however, that while the barren area is shown to constitute a considerable proportion of the whole bottom, much of it is so related to the productive bottom that it could not be eliminated under any scheme permitting of practical administration.

2. The second alternative—the total abolition of the public grounds and its corollary, the opening of the whole area for leasing—is drastic. On broad economic grounds the proposition is as logical and legitimate as the sale of public timber land or the breaking up of the great public ranges of the West into holdings in severalty, and, as the oyster is sessile, it has nothing in common with an alienation of the common fishery for nomadic species. The law has already recognized that under conditions an oyster in situ may be property, while a wandering fish can not become such until caught. The breaking up of the public grounds into leaseholds under private control would increase their productiveness precisely as the breaking up of the common ranges of the West has resulted in economic efficiency and greater productiveness. This course would, furthermore, yield a return to the State, where there is now a net outlay for policing the public grounds, though this aspect of the matter is one which should always be held subservient to the major consideration—the welfare and prosperity of the citizen.

On the other side of the question it is necessary to consider the effect of so drastic an innovation upon the welfare of a large body of persons whose livelihood in part is at present dependent upon the situation to which the policy of the State has given the aspect of presumed permanency. Immediately upon the alienation of the public beds the men engaged on them for part of the season are, for the time being, forced from the category of independent workers into that of employees, unless they themselves elect to take up

bottoms in severalty. The value of this objection is mainly sentimental, but is not less real on that account.

3. The third course mentioned, the retention of the actually productive bottom for the use of the public and the opening of all barren bottom practicable for leasehold from the State, is essentially a compromise between the other two and presents fewer difficulties than either. The valid objections to it are mainly concerned with administration. By retaining the present natural beds intact the tongers would be left in possession of everything of value to which they now have access, while the opening of the barren bottoms for lease would make productive considerable acres now valueless to all. The tongers would still have the option of independent work on the natural rocks; they would have increased opportunities of employment by the planters; and some of them could themselves lease bottoms for their own use. In every way it would appear to be economically advantageous to the industry and the State.

In considering the subject, however, it should be borne in mind that, while this report shows a preponderance of barren bottom within the public grounds, much of it, owing to its location, is practically incapable of separation from the natural rocks. An inspection of the chart will show that many of the barren bottoms are between or in the midst of naturally productive bottoms. To exclude them would make necessary an undue multiplication of the public grounds, with an attendant difficulty in policing.

Effectually to prevent depredations on the natural rocks under the guise of work on adjoining planted grounds, which is a difficulty with which the oyster police will have to contend, the public areas should be as few and as compact as possible, and the boundary lines should be straight and easily defined. For this reason the public grounds to be established must, for very practical considerations, necessarily include a considerable proportion of barren bottom. Any readjustment of the lines of the Baylor survey should be based on reasonable compromise and adopted only after careful consideration by the State. It is believed that the foregoing descriptions and the accompanying charts will furnish a reliable basis for a revision, should the State deem it wise to undertake it.

DESCRIPTION OF CHARTS.

The public grounds are platted from the published sheets of the Baylor survey, and their boundaries are shown in broken black lines.

The depths, which are expressed in feet as referred to mean low water and the symbols designating the consistency of the bottom, are the characteristics selected from a large number of observations. The oyster beds are included within solid red lines, and the density of the oyster growth is indicated by the relative intensity of the shading, and is based on the quantity of culled oysters which can be taken by a tonger working nine hours per day, not including the time occupied in culling.

Chart 1 covers the area from which market oysters only may be removed, and the bases of the classifications of oyster growth are as follows: Dense, yielding over 8 bushels of market oysters per day's tonging; scattering, between 5 and 8 bushels; very scattering, between 3 and 5 bushels; depleted, under 3 bushels.

Chart 2 embraces the beds of the upper part of James River, on which the cull law is inoperative so far as it pertains to the size of the oysters, and which are therefore devoted to the production of seed oysters for replanting. The classification is as follows: Dense, yielding over 12 bushels of seed oysters per day's tonging; scattering, between 8 and 12 bushels; very scattering, between 4 and 8 bushels; depleted, under 4 bushels.

The unshaded areas within the boundaries of the public beds as charted represent barren bottom.

THE FISHERIES OF ALASKA IN 1909.

By MILLARD C. MARSH, *Agent at the Salmon Fisheries of Alaska,*
and
JOHN N. COBB, *Assistant Agent.*

SUMMARIZED STATISTICS OF ALASKA FISHERIES.

As in the similar reports for previous years, the District of Alaska is considered in the four geographic sections generally recognized, as follows: Southeast Alaska, embracing all that narrow strip of mainland, and the numerous islands adjacent, from Portland Canal northwestward to and including Yakutat Bay; central Alaska, the region on the Pacific, or south side, from Yakutat Bay westward, including the Aleutian chain; western Alaska, the shores of Bering Sea, and islands in this sea; and arctic Alaska, from Bering Strait to the Canadian border.

With the exception of arctic Alaska and a portion of central and western Alaska, practically all of the fishing localities were visited by one or the other of the agents. Statistics of the yield of fur seals from the Pribilof Islands were obtained through the courtesy of the agent at the fur seal islands, while figures for the other aquatic furs (except the coast fur seals and sea otter) and skins, also whalebone and walrus ivory, were obtained from the custom-house records at Juneau. Considerable commercial fishing is carried on in the Yukon River and its tributaries, where fish wheels, nets, and spears are employed, but unfortunately it has been found impossible so far, owing to the short time available each season and the few agents employed, to extend the inspection work over this large region, or to secure data showing the extent of the fisheries there.

Owing to the impossibility of the agents' visiting arctic Alaska in the limited open season, thus making it difficult to secure accurate data, no attempt has been made to show the number of persons employed and the investment in the fisheries of this large region, although certain of the products are shown in the proper table. It has also been found an impossibility to secure even approximate

data as to the persons engaged or the investment in the hunting of aquatic animals (except fur seals and sea otters), which is general among the natives.

As in previous years, by far the greater part of the fishery products of Alaska are marketed outside the district, but a steadily increasing local demand is noticeable, especially in the case of the hitherto somewhat neglected minor species.

PERSONS ENGAGED.

The number of persons engaged in the fisheries of Alaska in 1909 was 12,588, of whom 4,487 were engaged directly in fishing, 7,520 in the canneries, salteries, and at other shore work, and 581 employed on the transporting vessels. This total is a loss of 749 from the number employed in 1908, due to the closing of several canneries temporarily, owing to the expected large quadrennial run on Puget Sound. The fact that the fishermen act as sailors on the transporting ships to and from the salmon canneries and salteries explains the small number of transporters shown in the table.

PERSONS ENGAGED IN THE ALASKA FISHERIES IN 1909.

Grand total	4,686	2,181	5,721	12,588

INVESTMENT.

The total investment in the fisheries was $9,881,682, a decrease of $438,102, due to causes outlined elsewhere. The item of outfit, as

related to fishing and transporting vessels, has been added to the value of the vessels. The item of cash capital was eliminated in the 1906 report, and this procedure has been followed ever since. Western Alaska leads in the total value of investment, followed by southeast and central Alaska, in the order named. The principal forms of apparatus all show small decreases in the number used as compared with 1908, the decrease in the number of traps alone being 13.

INVESTMENT IN THE ALASKA FISHERIES IN 1909.

[a] Aggregate length of 500 yards.
[b] Includes also value of 14 harpoons.
[c] Aggregate lentgh of 33,670 yards.
[d] Aggregate length of 36,930 yards.
[e] Aggregate length of 301,480 yards.

PRODUCTS.

The total quantity of products was 201,983,238 pounds, valued at $11,181,388, a decrease of 15,830,177 pounds and $666,055 from 1908, the greater part of the decrease being in salmon products. Except for salmon bellies and backs, fertilizer, oil, furs, and hides, the weights are round weights, or the weights of products when first taken from the water; for prepared products the weights are shown in the subsidiary tables of the report. As the packing establishments almost invariably catch their own fish, it has been found practically impossible to show the value of the products as they leave the fishermen's hands, hence the values shown are for the prepared products.

Products of Alaska Fisheries in 1909.

[l] Represents 50 skins.

THE SALMON INDUSTRY.

The season of 1909, while not so good as that of the previous year, which was the best the fishermen have ever had, was excellent so far as the quantity of fish obtained was concerned. The prices received for the cheaper grades, however, were not so remunerative as in some previous seasons.

The run in southeast Alaska, except in the lower portion, was very good, but the cannery men packed no more of the cheaper grades than they felt could be disposed of. As a result the catch of humpback salmon was 4,734,525 less and of dog salmon 1,069,269 less in number than in 1908.

In central Alaska the run in the neighborhood of Karluk fell off very materially as compared with 1908, but in Chignik the usual good run appeared, and the Alaska Packers Association sent to its Karluk canneries 54,605 red salmon, while the Northwestern Fisheries Company transferred to its Uyak cannery 100,950 red salmon.

In western Alaska the ice in Bristol Bay was found to be very troublesome this year, and some of the supply ships found difficulty in reaching their plants in time to get ready for the opening of the season. The steamer *Nushagak*, of the Alaska Packers Association, was held seven days in the ice pack not far off the mouth of Nushagak Bay. With the exception of the Ugashik and Ugaguk rivers and the Nushagak Bay region the runs were fairly good. The falling off in the latter region has been discussed in detail elsewhere in the report. In order to help out the canneries on the Nushagak and Ugaguk, canneries on the Naknek and Kvichak, owned by the same companies, sent to the Nushagak 123 king salmon and 289,688 red salmon, and to the Ugaguk River 12,178 red salmon.

In the Nushagak Bay the weather was especially bad during the greater part of the season, and as a result eight fishermen lost their lives through the capsizing of their boats.

PLANTS IN OPERATION.

Following is a list of the plants operated during the season of 1909:

Name.	Location.
Southeast Alaska:	
Canneries—	
Alaska Packers Association	Loring and Wrangell.
Northwestern Fisheries Co	Quadra, Hunter Bay, Santa Ana, and Dundas Bay.
William Duncan	Metlakahtla.
C. A. Burckhardt & Co	Yes Bay.
F. C. Barnes	Lake Bay.
Shakan Salmon Co	Shakan.
North Pacific Trading and Packing Co	Klawak.
Pillar Bay Packing Co	Pillar Bay.
Pacific Coast and Norway Packing Co	Petersburg.
John L. Carlson	Taku Harbor.
George T. Myers & Co	Sitkoh Bay.
Thlinket Packing Co	Funter Bay.

Name.	Location.
Southeast Alaska—Continued.	
Canneries—Continued.	
Pacific-American Fisheries	Excursion Inlet.
Columbia Canning Co	Haines.
Yakutat and Southern Ry. Co	Yakutat.
Salteries, etc.—	
Mrs. A. E. King	Sunny Point.
James Thompson	Skowl Arm.
Ketchikan Fisheries Co	Nakat Inlet.
Louis Peterson	Threemile, Kupreanof Island.
Fred. Brockman	Sarkaar.
R. E. Linton	Grace Harbor, Dall Island.
Knute Hauge	Wrangell Narrows.
M. E. Lane	Thorne Bay.
Walter C. Waters	Holbrook.
John H. Mantle	Olive Bay.
Vendsyssel Packing Co	Port Vaughn.
Rasmus Engee	Wrangell.
E. L. Skog	Petersburg.
J. Lindenberger (Incorporated)	Ketchikan, Egg Island, and Douglas.
Carlson & Holst	Chilkat Inlet.
Malcolm Campbell	Alsek River.
K. J. Johansen	Ideal Cove.
Engelbr. Wiese	Ketchikan and Cape Fanshaw.
George Scove	Kake.
Central Alaska:	
Canneries—	
Alaska Packers Association	Chignik, Karluk (2), Alitak, and Kasilof.
Northwestern Fisheries Co	Orca, Uyak, and Chignik.
Salteries, etc.—	
Alaska Commercial Co	Kodiak.
Blodgett & Blinn	Do.
J. A. Herbert & Co	English Bay.
Brostrup Amondsen	Ozenoy.
Osmund & Andersen	Thin Point.
Western Alaska:	
Canneries—	
Alaska Packers Association	Naknek River (2), Ugaguk River, Nushagak Bay (2), and Kvichak Bay (2).
Northwestern Fisheries Co	Nushagak Bay.
Red Salmon Canning Co	Ugashik River.
North Alaska Salmon Co	Nushagak Bay, Lockonok, Kvichak River, and Ugaguk River.
Naknek Packing Co	Naknek River
L. A. Pedersen	Kvichak Bay.
Alaska-Portland Packers Association	Nushagak Bay.
Columbia River Packers Association	Do.
Alaska Fishermen's Packing Co	Do.
Salteries, etc.:	
Lagoon Salmon Co	Nelson Lagoon.
Peter M. Nelson	Igushik River.
Nelson, Olsen & Co	Kvichak Bay.

HATCHERIES.

Seven salmon hatcheries were operated during the season of 1908–9, as follows:

Name.	Location.	Owner and operator.
Yes Lake	Yes Lake	United States Bureau of Fisheries.
Afognak	Afognak Island	Do.
Fortmann	Naha Stream	Alaska Packers Association.
Karluk	Karluk River	Do.
Klawak	Klawak Lake	North Pacific Trading and Packing Co.
Hetta	Hetta Lake	Northwestern Fisheries Co.
Quadra	Quadra Lake	Do.

Although the streams in southeast Alaska were unusually high in September, owing to the excessive rains (29 inches of rain fell at Yes

Lake hatchery during this month) the hatcheries were able to prevent their dams and racks from being washed out, and all, with the exception of Fortmann hatchery, where the water was so high as to interfere seriously with seining, secured all the eggs they were able to handle.

The Northwestern Fisheries Company has constructed at its Hetta hatchery a large corral of wire netting in which to retain the fry for a short time.

OUTPUT OF THE SALMON HATCHERIES OF ALASKA.

Hatcheries.	Year ending June 30, 1909.					
	Red, or sockeye.		Coho, or silver.		Humpback.	
	Eggs taken.	Fry liberated.	Eggs taken.	Fry liberated.	Eggs taken.	Fry liberated.
Yes Lake	50,000,000	48,653,000	17,000	9,900		
Afognak	46,380,000	39,325,870				10,000
Fortmann	24,465,000	22,785,000				
Karluk	40,320,000	37,105,000				
Klawak	3,500,000	3,200,000				
Hetta	8,400,000	8,143,000				
Quadra	3,325,000	3,025,750				
Total	176,390,000	162,237,620	17,000	9,900		10,000

Quadra	9,660,000		
Total	264,248,000	5,000	499,400

a No report received.

One of the most interesting fish-cultural experiments undertaken on the Pacific coast is that of Mr. John C. Callbreath in southeast Alaska. Mr. Callbreath has been a resident of Alaska for many years, and was manager of the Point Ellis salmon cannery until it was destroyed by fire in 1892. He was one of the first who saw that the apparently inexhaustible salmon runs in Alaska could not last forever, and in 1892 opened a rude little hatchery on Point Ellis Stream. A high September tide carried away the eggs; but the burning of the cannery left him with leisure to carry out a plan which he had been revolving in his mind for some time. This was to select a stream that under normal conditions carried but a few thousand red salmon, and by artificial propagation increase the production to hundreds of thousands, with the ultimate hope that if

he was successful the government would enact a special law making all the increase his own property.

The stream selected for the experiment is at the head of McHenry Inlet, on Etolin Island, in southeast Alaska. It is small, about one-half mile in length, and, like most of the streams in this region, flows over a rocky and bowldery bed between heavily wooded shelving banks. At its head is a small lake, 42 feet above tide water. The stream was considered to have a run of from 3,000 to 5,000 red salmon, a number too small to attract the fishermen, who rarely visited it. In 1892 a small hatchery was built on the stream about 200 yards from the mouth. In the spring of 1893, however, it was removed to the lake, the first location having been found not to be suitable.

From the very beginning it was decided to exclude all but the most desirable species from the lake. To accomplish this, dams were built across the stream, with racks below them, at a point about 100 yards from salt water, where an islet divides the stream into two parts. The dam and fence on the western side of the islet allow nothing to pass. The fence on the eastern side has a trap opening, admitting the fish to the foot of the dam. Here the red and coho salmon are lifted by dip nets to the pool above, from which point they can ascend quickly to the lake. Nothing can enter the lake which is not passed over the dam by hand. In addition to keeping out the humpback and dog salmon and all trout, the lake has been carefully fished and all enemies of the salmon that could be caught have been removed.

Under these exceptionally favorable conditions the work was carried on from 1892 until the spring of 1906, when Mr. Callbreath was obliged to discontinue the operation of the hatchery, owing to lack of funds and failing eyesight, the latter misfortune resulting a year or two later in total blindness. He still maintained the dam and racks, however, employing a man to lift the fish over the dam as usual each fall.

The following statement shows the number of red salmon passed over the dam each season:

1892	3,000	1901	2,924
1893	3,010	1902	5,077
1894	4,463	1903	5,648
1895	5,026	1904	7,432
1896	3,627	1905	7,623
1897	2,589	1906	7,320
1898	2,010	1907	7,542
1899	2,233	1908	slightly over 3,000
1900	3,854		

It is very evident from the above that Mr. Callbreath's expectations have been far from realized, but he is entitled to great credit for the persistence with which he has carried on the experiment despite the natural difficulties encountered and the almost overwhelming physical afflictions under which he has labored for the past four years.

STATISTICS.

CATCH IN 1907, 1908, AND 1909.

Following is a table showing, for the geographic sections, by apparatus and species and by species alone, the number of salmon caught in the years 1907, 1908, and 1909.

The noticeable feature of the table is the relatively small decrease in the catch of red salmon with gill nets as compared with the large decreases shown for seines and traps. The catch with lines shows a large increase over the two previous years, due to the rapid development of the king salmon fishery.

All species, except king salmon, show a decrease from 1908, this decrease being especially noticeable in humpback salmon, which dropped off 5,614,673 in number. The total decrease in 1909 as compared with 1908 is 8,612,371 in number.

CANNING.

When the season opened practically the only stocks left in the canners' hands were pink salmon, these having proved difficult to

dispose of even at the very low prevailing prices. A few of the canners left these fish at their plants in Alaska during the winter, in order to save the storage charges on the Sound. The price of pink and dog salmon continued to decline this year, but a slightly better demand developed and it is hoped that as the accumulated pack on Puget Sound decreases the demand for the cheap grades from Alaska will eventually equal the supply. All other grades are in excellent demand at present and but few cases were left in the packers' hands at the close of this year.

Owing to the expected quadrennial heavy run of sockeye salmon on Puget Sound, several cannerymen who operate there and in Alaska shut down their Alaska plants this season and devoted all their energies to the Sound. Among those in southeast Alaska were the cannery of Gorman & Co., at Kasaan, and of the Astoria and Puget Sound Packing Company, in Excursion Inlet. The Pyramid Harbor cannery of the Alaska Packers Association was not operated this year and probably will not be again. In western Alaska the Coffee Creek cannery of the Alaska Packers Association, which burned in 1906, was rebuilt and operated this season. The Bradford cannery of the Alaska Packers Association, on Nushagak Bay, was not operated this year, nor, owing to the loss of its supply ship, as noted elsewhere, was the Wood River cannery of the Alaska Salmon Company.

The superintendent of the Sitkoh Bay cannery, in southeast Alaska, reports getting from Necker Bay, on the western shore of Baranof Island, a number of red salmon which ran 24 to the case—exceptionally small fish. They are said to have been very red in color and especially good for canning. Twenty-five of the smallest ones were opened and found to be all mature males.

Persons engaged.—The fishermen engaged this year numbered 2,992, of whom almost two-thirds were white. The cannery employees numbered 7,100, of whom all nationalities except the whites, who increased 312 in number, show decreases as compared with 1908. The transporters numbered 430. All branches of the industry show decreases as compared with 1908. In all, 10,522 persons (4,391 whites, 1,998 Indians, 1,992 Chinese, and 2,141 Japanese) were employed, as compared with 11,085 persons (4,403 whites, 2,250 Indians, 2,017 Chinese, and 2,415 Japanese) employed in 1908.

PERSONS ENGAGED IN THE SALMON-CANNING INDUSTRY IN 1909.

Occupation and race.	Southeast Alaska.	Central Alaska.	Western Alaska.	Total.
Fishermen:

Grand total	3,343	1,643	5,536	10,522

Investment.—There were 114 steamers and 39 sailing vessels engaged in transporting supplies and the pack.

Gill nets were the principal form of apparatus in use, by far the greater number being employed in western Alaska. Purse seines and spears were used only in southeast Alaska, haul seines and traps were most numerous there. All forms of apparatus except gill nets show a decrease in 1909 as compared with 1908.

There were 45 canneries in operation (19 in southeast Alaska, 8 in central Alaska, and 18 in western Alaska) as compared with 50 (23 in southeast Alaska, 8 in central Alaska, and 19 in western Alaska) in 1908.

Output.—The table of products shows the quantity and value of each species packed, with size and style of can. As usual, western

Alaska leads in the quantity and value of the pack, followed by southeast and central Alaska, in the order named. Red, or sockeye, salmon predominate in all sections, but more especially in the western, where they form the bulk of the pack. Humpback, or pink, salmon predominate in southeast Alaska. Very few one-half pound and 1-pound flats were packed this year, although quite a number were put up in 1908.

1-pound tall	185,444	825,926	355,349	1,625,371	1,071,123	4,858,756	1,611,916	7,310,053
Total	280,542	1,094,423	358,285	1,640,910	1,074,667	4,875,217	1,713,494	7,610,550
Grand total	860,319	2,537,838	391,054	1,771,877	1,152,296	5,128,437	2,403,669	9,438,152

[a] All pound cases contain 48 1-pound cans; the ½-pound cases contain 48 ½-pound cans. Reduced to a common basis of cases containing 48 1-pound cans the pack is 2,395,477½ cases.

Comparison of pack of 1906, 1907, 1908, and 1909.—Of the four years in question, the pack of 1908 surpassed all the others both in quantity and value, having been the largest made since the inception of the industry. The pack of 1909 is next in size and value, followed by 1906 and 1907, in the order named, except that the value of the 1907 pack is greater than that of 1906. The pack of red salmon was larger in 1909 than in any previous year.

Taking the "1-pound tall," which is the common-size can, as a basis of comparison, it is seen that cohos averaged $4.07 per case, an increase of 9 cents per case over 1908 and 16 cents over 1907; dog, or chum, salmon averaged $2.28 per case, a decrease of 26 cents as compared with 1908 and of 70 cents as compared with 1907; humpback, or pink, salmon averaged $2.40 per case, a decrease of 29 cents as compared with 1908 and of 76 cents as compared with 1907; king salmon averaged $4.32 per case, an increase of 12 cents as compared with 1908 and of 14 cents as compared with 1907; while the red, or sockeye, salmon averaged $4.53 per case, an increase of 1 cent per case as compared with 1908 and a decrease of 6 cents per case as compared with 1907.

PICKLING.

The Department has construed the Alaska fisheries law to the effect that the packing of salmon bellies without making some economic use of the backs is contrary to the requirements of section 8 of that law. This decision went into effect on January 1, 1909, and considerable interest attached to the probable influence it would have on the packing of bellies, which had hitherto been a quite important part of the pickling business. A number of the salteries gave up the packing of bellies altogether and devoted their attention to the whole fish or else closed up their plants. A few continued packing the bellies and made various use of the backs, such as pickling, drying, and smoking, while one salter extracted the oil from them.

It is the aim of the Department to break up the old wasteful practice by which from one-half to two-thirds of the edible portion of the salmon was thrown away in order that the belly might be pickled, and all who continue packing bellies will be required to furnish satisfactory proof of the economic use of the backs.

The salteries met with fair success this season. There was, however, a decrease in the pack, due largely to the fear of the packers that prices would not be as remunerative as in some earlier years, and later events justified these fears. There has been but little foreign

demand since the season ended and as a result the market has been rather weak.

The pickling and mild-curing plant of the San Juan Fishing and Packing Company, at Kenai, on Cook Inlet, was not operated this season, nor was the pickling plant of the Alaska Packers Association on the Ugashik River, in western Alaska.

Persons engaged.—This year 396 persons (of whom 237 were fishermen, 130 shoresmen, and 29 transporters) were employed, a decrease of 144 as compared with 1908.

PERSONS ENGAGED IN THE SALMON-PICKLING INDUSTRY IN 1909.

Grand total	111	200	85	396

Investment.—There were 16 salteries (8 in southeast Alaska, 5 in central Alaska, and 3 in western Alaska) in operation, a decrease of 19 as compared with 1908. In addition some of the canneries and mild-curing plants also pickled their surplus catch, and while the product has been included in the present table the men and investment could not be separated from the statistics of the other branches of the industry.

Output.—The output amounted to 26,915 barrels and 6,997 half barrels, with a total value of $208,758, a decrease of 9,034 barrels, an increase of 750 half barrels, and a decrease of $143,949, as compared with 1908. The pack of humpback bellies fell off from 517 barrels and 2,346 half barrels in 1908 to 738 barrels in 1909. The pack of red salmon bellies fell off from 1,895 barrels in 1908 to 942 barrels in 1909. No dog salmon bellies were packed in 1908. Red salmon forms the bulk of the pack. Of the backs left after the humpback bellies had been packed 56 barrels were pickled.

MILD CURING.

The packing of mild-cured salmon was confined this season to southeast Alaska, the plant of the San Juan Fishing and Packing Company, at Kenai, on Cook Inlet, central Alaska, not being operated. This business is proving one of the most attractive in southeast Alaska, where king salmon are to be found throughout the greater part of the year. The chief danger at present is that it may be overdone and the supply of kings seriously depleted.

The principal trouble the dealers experience at present is in getting rid of the white-meated king salmon with the least possible loss. These fish average about one-fourth of the total catch, and the fishermen insist that the dealers shall take them along with the others, which they do at a considerably lower price. Early in the season many of them are shipped fresh to the Puget Sound ports, but after the kings begin to run in the Sound this is unprofitable.

Persons engaged.—This year 521 persons (of whom 446 were fishermen, 55 shoresmen, and 20 transporters) were engaged in the mild-curing industry. A number of others also engaged in it for limited periods, but as their work in connection with other branches of the industry was more important they have been included with those.

Investment and products.—There were 11 fixed plants, i. e., plants with permanent buildings and a chief business of mild-curing salmon, operated in southeast Alaska this year. A considerable part of this industry is done by schooners and launches, which catch the fish in small boats and pack them aboard the vessels, and move from place to place with the schools of salmon. Some of these vessels also engage in the catching of halibut, or of salmon for the canneries. In the following tables, whenever these branches exceed in importance the mild-curing work of the vessels, the latter have been shown in the more important fishery, only the catch appearing in the table. The pack amounted to 2,292 tierces, valued at $149,300, an increase of 914 tierces and $71,489 over 1908.

FRESH SALMON.

The demand from Puget Sound for fresh Alaska king salmon was excellent this year, and during most of the spring months the prices realized were very good. A considerable proportion of the shipments comprised white-meated king salmon and small red-meated kings which were not suitable or were in too great abundance to be used by the mild curers. The business was confined to southeast Alaska, and Ketchikan, Wrangell, Petersburg, Douglas, and Juneau were the principal shipping points.

During the course of the year 42,623 king salmon, valued at $39,707, were disposed of in a fresh condition, principally outside of the district. This was an increase of 6,337 fish over 1908. A considerable quantity of red, coho, and humpback salmon were also disposed of locally in a fresh condition.

MINOR PRESERVING PROCESSES.

Dry salting and drying.—At a few places in central Alaska the bellies of red and coho salmon are cut out and pickled, after which the backs are dried in the sun, and the resulting product, called "ukalu," used for fox food at the fox ranches.

The dry salting of dog salmon for food has almost ceased, but 71,600 pounds, valued at $1,038, being prepared. During the Russian-Japanese war this was quite an important industry.

Smoking.—A delicious smoked product, known locally as "beleke," is put up at Kodiak and several other places, the backs of red and coho salmon being utilized. A full description of the method of curing appears in the 1908 report of the salmon agents.

Freezing.—The only establishment engaged in freezing salmon is at Taku Harbor, in southeast Alaska. The species handled this year were coho and dog salmon. Other species of fish frozen were halibut, black bass, black cod, and steelhead trout.

MISCELLANEOUS FISHERY NOTES.

DISASTERS.

As the ship *Columbia*, under charter to the Alaska Salmon Company, which has a cannery on Wood River, a tributary of Nushagak Bay, was on her way from San Francisco to the cannery with the season's outfit and the canning and fishing crews, composed of 53 Italians, 96 Japanese, and 45 Americans and Scandinavians, she was driven on the eastern shore of Unimak Pass, about 6 miles from Scotch Cap light-house, early in the morning of April 30, and became a total wreck, the crews barely escaping. The *Columbia* was a full-rigged ship of 1,327 net tons, built in Bath, Me., in 1871. Her

dimensions were 205.9 feet length; breadth, 40 feet; and depth, 24 feet. She had been engaged in transporting cannery supplies for a number of years, and was owned by Capt. Henry Nelson, of San Francisco. As a result of this wreck the cannery of the Alaska Salmon Company was not operated this season, the time being too short to send up a new outfit.

The steam tug *Uyak*, of 12 net tons, which was employed in carrying salmon from the seines on Karluk Spit to the Uyak Bay cannery of the Northwestern Fisheries Company, was lost at Karluk during a terrific northeast gale on September 19. The crew narrowly escaped. The *Uyak* was built at Alameda, Cal., in 1901, and belonged to the company operating her.

KING SALMON FISHERY.[a]

King salmon began to appear in the lower part of southeast Alaska in March, but it was not until about the middle of April that they were found in any abundance. From then until about the middle of June, when fishing ceased in most places for about six weeks, the catch was very good. In May reports from Portland Canal were to the effect that a large run of kings had appeared there, but no effort was made to go for them. In July the kings were found to be numerous in Port Malmesbury, just inside Cape Decision, in Tebenkof Bay and in Gedney Harbor in Chatham Strait, on the west shore of Kuiu Island.

It is reported, with what truth we do not know, that king salmon are found in the deep pools of the Stikine River, also near the Hot Springs in the same river, in winter, and that the Indians cut holes in the ice and spear the fish.

The sportsmen of Ketchikan are agreed that the white-meated king salmon are gamier than the red-meated ones. The latter generally break water once and then go to the bottom, while the former remain near the surface and fight it out, breaking water five or six times.

One of the officers of the revenue cutter *Thetis*, on October 8, 1906, caught with hook and line, using artificial bait (Wilson spinner, single hook), from the wharf at Unalaska, four king salmon which weighed 29, 24, 22, and 20 pounds, respectively. They were all in fine condition and had been feeding on herring.

A white-meated female king salmon, caught with a trolling line and landed at Ketchikan about the middle of April, weighed 69¾ pounds, and measured 4 feet 6 inches from tip of snout to tip of tail and 18 inches across the widest part of the middle.

---

[a] A detailed description of this fishery appears in the 1908 report of the salmon agents, Bureau of Fisheries Document No. 645.

Mr. H. C. Bergman reports that there was delivered to his mild-curing plant at Egg Island, near Klawak, a white-meated female king salmon which weighed, without the head, 101 pounds.

TROLLING FOR SALMON OTHER THAN KINGS.

Other species of salmon, in addition to the king, are found to take the trolling hook. For several weeks in July trollers in Union Bay, in southeast Alaska, caught a number of cohos and humpbacks while trolling for kings. The humpbacks were caught mainly with a spoon, no bait being used. Most of them appeared to have been feeding on needlefish and herring, according to the cutter who dressed them. A few red salmon are reported to have been caught on the trolling line by fishermen operating for king salmon in the neighborhood of Mary Island, near Dixon Entrance. Several fishermen report having in previous years frequently taken dog salmon on a hook in the bays along Chatham Strait.

SALMON IN SEAL'S STOMACH.

This spring the assistant fur-seal agent on St. George Island, upon opening the stomach of a seal killed on the island, found it full of salmon. The fact is worthy of note as being the first instance, at least in recent years, where the stomach of a seal killed on the islands has been found to contain food of any kind, owing to the seals' habit of digesting their food before coming ashore.

MARKED SALMON.

A cutter for the Pacific Coast and Norway Packing Company at Petersburg reported a king salmon this season which had a crescent-shaped piece cut out of the lower lobe of the tail.

During July and early in August an Indian fishing on Karta Bay, Prince of Wales Island, caught about 17 red salmon from which the adipose fin had been removed. He reported this to the superintendent of the cannery at Loring, who immediately sent out orders to his scowmen to keep such fish separate from the general lot, and as a result 5 more were brought to Loring previous to August 5. One of the present authors saw 2 of the marked fish on the latter date, one of which measured 26 inches and the other 29 inches in length.

At Yes Lake hatchery 4 adult redfish lacking both ventral fins were taken in the 1909 spawning run. These are returns from the Chamberlain marks of 1903, referred to in previous reports, and this is the fourth successive season during which a return has been received from this marking experiment. No return was obtained this

year, however, in Naha Stream itself, on which Fortmann hatchery is located and in which the original plant of marked fish was made.

For the first time a report has been received of a redfish lacking both ventrals taken outside of southeast Alaska. The Alaska Packers Association reports "several mature sockeye salmon" with these fins lacking at its Karluk hatchery during the 1909 spawning season. One of these was forwarded to the Bureau of Fisheries and on examination identified with the Chamberlain marked salmon. If it had been taken in the Naha or Yes Bay Stream, no question would have arisen over its identity as a marked fish, as the specimen does not differ essentially from the fish already recognized as marked returns. The great distance between the place where these fish were hatched and marked and the stream of the supposed return need not prevent a corresponding migration, but it is not to be inferred that there is any considerable interchange of this sort between these or other regions remote from each other.

The prolongation of the return from this very interesting marking experiment has been rather unexpected, and the next season's results will be awaited with additional interest.

FISHERY LAWS AND THEIR ENFORCEMENT.

NEEDS OF THE SERVICE.

The most urgent need of the Alaska salmon-inspection service is proper vessels for carrying on its work. In no part of Alaska are means of local communication other than very meager. The regular steamship lines visit only the more important points, and in some sections the calls of such steamers will not average more than one or two a month. Then, as they cover a wide area in their travels, the steamers can remain but a few hours at any one place, a time not sufficient for an inspector to look over the fishing grounds, which are usually off the regular line of travel. Even if these vessels were available, however, the inspectors should not be compelled to depend upon them, for the fishermen would in this event be able to prepare for the arrival of the vessel with the inspector aboard, and thus to conceal any illegality that might be in practice.

Owing to the lack of suitable vessels it was found impossible in 1908 and 1909 to inspect any of the fisheries of central Alaska. In these sections vessels of sufficient size and seaworthiness can not be chartered. In the protected waters of southeast Alaska launches can be used, but as they must, under present conditions, be chartered with their crews, it is almost impossible to prevent notification of the fishermen in advance. Frequently, also, when a launch is most needed, all of the few available will be under charter and the trip must be abandoned.

More inspectors, also, are needed in order to cover the territory properly. But it is useless to have these unless there are vessels available for their use. Under existing conditions the additional inspectors would merely be marooned for weeks at a time, and, as the salmon fishing season in central and western Alaska is comprised within four months' time at the most, almost nothing could be accomplished.

Three vessels are needed for this service. In southeast Alaska a comparatively small launch (about 60 feet long, 12 feet beam, and fitted with a 60-horsepower gasoline engine) would answer the purpose. In western Alaska a somewhat larger one would be required. For the work in central Alaska a much larger vessel is needed, one of at least 100 tons displacement, as the waters in this section are open and storms are frequent.

The Dominion of Canada, although having only about one-fifth as much coast line on the Pacific as Alaska, maintains two steamers, and is now building a third, for the purpose of protecting her fishing grounds.

COMPLAINTS AND PROSECUTIONS.

Two traps belonging to Mr. John L. Carlson (who operates a cannery at Taku Harbor), one located at False Point Retreat, on Mansfield Peninsula, Admiralty Island, and the other in Shelter Cove, on Shelter Island, were found by the assistant agent to be fishing during the weekly close season of July 3–5. Complaint was filed with the United States attorney at Juneau against the owner and the three watchmen in charge, Hans Andersen, Peter Antonick, and John Berich. At the preliminary hearing the United States commissioner discharged Mr. Carlson, as it was not satisfactorily proved that he had knowledge of the action of his men, but the watchmen were bound over to the grand jury. On August 21 the grand jury returned true bills against Hans Andersen and John Berich, the case against Peter Antonick having been dropped, as an investigation had developed that he was merely a temporary assistant to Andersen, the regular watchman. Upon arraignment in court on August 30 both defendants pleaded guilty and were fined $150 each and costs, which were paid.

Several Indians fishing in Karta Bay, Prince of Wales Island, having complained that one of the crews there had violated the weekly close season, an investigation was made, and as a result sworn complaint was made by the assistant agent before the United States commissioner at Ketchikan. George Kyan, an Indian, and his seine crew, all Indians, were arrested. At the preliminary hearing on July 19 George Kyan was held for the next grand jury meeting in Ketchikan, but the rest of the crew were discharged. As no grand jury was called for the October term in Ketchikan, the case had to go over until next year.

A pernicious method of fishing known as "jigging," which has been occasionally followed in Ketchikan Creek, was forbidden this year. In jigging a long line with a three-pronged grapnel is used, or else three heavy fishhooks tied back to back, at the end, and a heavy sinker secured on the line a short distance above the grapnel. In July and August the salmon are massed in the pool below the first falls and the fishermen throw the grapnel end of the jigger to the far side of the pool and then draw it back in a series of short, sharp jerks. The fish are so massed together that it is unusual when the hooks do not catch upon one or more salmon each cast. Most of them escape, however, terribly torn and mangled, and are frequently found dead at the bottom shortly after. As long as the few owners of this form of apparatus used it in securing salmon for their own use, the practice, though reprobated, was tolerated. It was discovered this season, however, that these jiggers were being rented to tourists while the steamers were lying at the docks, the tourists using them merely to catch the salmon for amusement, and leaving the carcasses usually to rot on the banks of the creek. The practice was therefore absolutely prohibited. In reality there never was necessity for this cruel form of apparatus, as the salmon are so abundant in the pools below the first falls that sufficient to supply all ordinary needs can be secured with the bare hands.

Another prohibition this year was against the tourists' practice of catching salmon with their hands as the fish struggle up the first falls in Ketchikan Creek. In many instances this has been done for the sole purpose of being able to boast of the feat, the fish being generally left on the banks to die. Sometimes, however, the fish are thought to be fit for food. As a matter of fact, all salmon found at the falls after about July 15 are practically worthless as food, although very valuable in keeping up the future supply if permitted to go on to the spawning beds.

As the salmon-fishing season was nearing its close, information was received that net fishing was being done in Eyak Lake and River. It is doubtful, under the law, whether this can be prevented unless these waters are set aside as spawning reserves, and in 1906 this action was recommended. The closing of the lake and river to commercial fishing would probably not seriously affect the packing interests, as the resources of the river have been so greatly reduced by excessive fishing in the past that they do not now afford a very material addition to the salmon supply of the region. Eyak Lake, is, however, one of the principal spawning regions in Prince William Sound, and should be protected to the fullest possible extent.

A letter from Golofnin Bay, Bering Sea, dated July 26, complained that the run of salmon in Fish River, a tributary of the bay, had become so depleted owing to hydraulic mining that the Eskimos who

had heretofore fished here for their own wants had been compelled to move down on the bay shore in order to carry on their fishery operations. In the latter place, during the last two years, according to the complaint, they have had to compete with Laplanders from Nome, who, by the use of large traps and gill nets, have so surrounded the small gill nets used by the natives that the latter have been unable to catch enough fish to provide for their wants during the winter months. As the complaint was received after the fishing season was over, nothing could be done in the matter this year.

LABELING OF CANNED SALMON.

Food inspection decision 105, issued March 10, 1909, by the board of food and drug inspection, Department of Agriculture, relates to the labeling of canned salmon and whitefish. As the subject is of importance to the canners of Alaska, that portion relating to salmon is reproduced herewith:

Many inquiries have been made of the Department regarding the nomenclature commonly employed in designating canned salmon. It is stated that inferior species of salmon are frequently canned and labeled with some name which is understood by the trade to indicate the presence of fish of an inferior variety, but which is not so understood by the consumer; as, for instance, "Alaska salmon." The Department is informed by the Bureau of Fisheries that the species of salmon in the United States are as follows:

1. *Oncorhynchus nerka.* Sockeye or sockeye salmon, blueback salmon, redfish, or nerka salmon.

2. *Oncorhynchus tschawytscha.* Chinook salmon, king salmon, quinnat salmon, tyee salmon, or spring salmon.

3. *Oncorhynchus gorbuscha.* Humpback salmon, pink salmon, or gorbuscha salmon.

4. *Oncorhynchus kisutch.* Coho salmon, silver salmon, or medium red.

5. *Oncorhynchus keta.* Calico salmon, keta salmon, dog salmon, or chum salmon.

6. *Salmo gairdneri.* Steelhead salmon, steelhead, hardhead, winter salmon, salmon trout, or square-tailed trout.

7. *Salmo salar.* Atlantic salmon.

Two additional species of landlocked salmon exist in certain New England and Canadian lakes. Neither of these nor the Atlantic salmon is ever canned. Considering this fact, and the further fact that many packers put up humpback and dog salmon under fancy names and thus sell them to consumers who may believe them to be of superior varieties, it is held that canned salmon should be labeled with one of the common names mentioned above as belonging to the species of fish canned.

LICENSE TAXES AND HATCHERY REBATES.

Under the provisions of the act for the protection and regulation of the fisheries of Alaska (approved June 26, 1906), the packers in Alaska are compelled to pay license fees or taxes on their season's output, as noted in the table following. The collection of these

license fees or taxes is in the hands of the clerk of the court of the judicial district in which the packer is operating. The law literally requires the packer to pay the license fee in advance, but as the fee is based upon the pack he makes, and it would be impossible in such an uncertain industry as fishing to estimate in advance exactly the quantity that will be packed, it is the custom to require the operator to apply for a license before beginning operations, and then at the end of the season make return of the amount due the district.

The following table shows the quantity of taxable fishery products prepared, the stated license tax on the product, and the total amount of tax received on each. It should be distinctly understood that the last item is merely approximate, being based upon returns on file at this Bureau, some of which are sworn and some estimated, and therefore perhaps varying somewhat from those sent to the clerk of the court. It is not probable, however, that the amount given will vary much either way from the correct amount as shown by the returns of the clerks.

LICENSE TAXES ON PREPARED FISHERY PRODUCTS.

Items.	Quantity prepared.	License tax.	Estimated amount of tax due.
Canned salmon	2,395,476 cases	4 cents per case	$95,819
Pickled salmon	33,441 barrels	10 cents per barrel	3,344
Mild-cured salmon	2,292 tierces [a]	40 cents per tierce	917
Dry-salted salmon in bulk	71,600 pounds	5 cents per 100 pounds	358
Fish oil	5,491 barrels	10 cents per barrel	549
Fertilizer [b]	1,155 tons	20 cents per ton	231
Total			101,218

[a] As the net weight of a tierce of fish is 800 pounds, this item is figured on a basis of 4 barrels to the tierce in working out the amount of tax.
[b] The fertilizer from whales has not been included.

Salmon hatching has been a more or less extensive enterprise of cannery proprietors ever since 1891, and the two larger establishments have been in operation continuously for nine and fourteen years past. Up to 1900 the work was entirely voluntary on the part of the packers. On May 2 of that year the following regulation was promulgated by the Treasury Department, which at that time had control of the Alaska salmon-inspection service:

7. Each person, company, or corporation taking salmon in Alaskan waters shall establish and conduct, at or near the fisheries operated by him or them, a suitable artificial propagating plant or hatchery; and shall produce yearly and place in the natural spawning waters of each fishery so operated red salmon fry in such numbers as shall be equal to at least four times the number of mature fish taken from the said fisheries, by or for him or them, during the preceding fishing season. The management and operation of such hatcheries shall be subject to such rules and regulations as may hereafter be prescribed by the Secretary of the Treasury. They shall be open for inspection by the

authorized official of this Department; annual reports shall be made, giving full particulars of the number of male and female salmon stripped, the number of eggs treated, the number and percentage of fish hatched, and all other conditions of interest; and there shall be made a sworn yearly statement of the number of fry planted and the exact location where said planting was done.

On January 24, 1902, this regulation was amended so as to require the planting of "red salmon fry in such numbers as shall be equal to at least ten times the number of salmon of all varieties taken from the said fisheries."

Although the regulation was mandatory, but few of the packers obeyed it, some because no suitable place was to be found within a reasonable distance of their plants, others because the establishment and operation of such a hatchery would cost more than their returns from the industry justified, while still others absolutely ignored it. A few continued to operate the hatcheries they had established prior to the promulgation of the regulation in question, and even established new ones, so as to conform more closely to its requirements. But as a result the packers who obeyed the regulation were placed under a heavy financial handicap. They were compelled to pay all the expenses of keeping up and operating their hatcheries, and at the same time to pay the regular license fees or taxes on their pack of fishery products, while those who evaded or disobeyed the law merely paid the license tax.

The injustice of this arrangement was patent on its face, and when in 1906 a comprehensive revision of the law was made by Congress provision was made for reimbursing in the future those cannery men who operated salmon hatcheries. The section covering this point reads as follows:

SEC. 2. That the catch and pack of salmon made in Alaska by the owners of private salmon hatcheries operated in Alaska shall be exempt from all license fees and taxation of every nature at the rate of ten cases of canned salmon to every one thousand red or king salmon fry liberated, upon the following conditions:

That the Secretary of Commerce and Labor may from time to time, and on the application of the hatchery owner shall, within a reasonable time thereafter, cause such private hatcheries to be inspected for the purpose of determining the character of their operations, efficiency, and productiveness, and if he approve the same shall cause notice of such approval to be filed in the office of the clerk or deputy clerk of the United States district court of the division of the District of Alaska wherein any such hatchery is located, and shall also notify the owners of such hatchery of the action taken by him. The owner, agent, officer, or superintendent of any hatchery the effectiveness and productiveness of which has been approved as above provided shall, between the thirtieth day of June and the thirty-first day of December of each year, make proof of the number of salmon fry liberated during the twelve months immediately preceding the thirtieth day of June, by a written statement under oath. Such proof shall be filed in the office of the clerk or deputy clerk of the United States district court of the division of the District of Alaska wherein such hatchery is located, and when so filed shall entitle the respective hatchery

owners to the exemption as herein provided; and a false oath as to the number of salmon fry liberated shall be deemed perjury and subject the offender to all the pains and penalties thereof. Duplicates of such statements shall also be filed with the Secretary of Commerce and Labor.

It shall be the duty of such clerk or deputy clerk in whose office the approval and proof heretofore provided for are filed to forthwith issue to the hatchery owner, causing such proofs to be filed, certificates which shall not be transferable and of such denominations as said owner may request (no certificate to cover fewer than one thousand fry), covering in the aggregate the number of fry so proved to have been liberated; and such certificates may be used at any time by the person, company, corporation, or association to whom issued for the payment pro tanto of any license fees or taxes upon or against or on account of any catch or pack of salmon made by them in Alaska; and it shall be the duty of all public officials charged with the duty of collecting or receiving such license fees or taxes to accept such certificates in lieu of money in payment of all license fees or taxes upon or against the pack of canned salmon at the ratio of one thousand fry for each ten cases of salmon. No hatchery owner shall obtain the rebates from the output of any hatchery to which he might otherwise be entitled under this act unless the efficiency of said hatchery has first been approved by the Secretary of Commerce and Labor in the manner herein provided for.

While the efficiency and productiveness of the private salmon hatcheries must be favorably certified to by the agents of this Department before they become eligible to participate in the provisions of the law, the passing upon the correctness of the returns made by the hatchery men, the issuance of the rebate certificates and their receipt later in payment of license fees or taxes are matters solely within the province of the clerk of the court of the judicial district in which the hatchery is located, the law merely requiring the owner to forward to the Department a sworn copy of his report to the clerk.

The following table shows the name of owner, location of each private salmon hatchery operated during the fiscal year ending June 30, 1909, the number of salmon (all reds) liberated, and the amount of rebate certificates due each hatchery:

REBATES CREDITED TO PRIVATE SALMON HATCHERIES IN 1909.

Owner.	Location.	Salmon fry liberated.	Rebate due.
Alaska Packers Association	Naha Stream	22,785,000	$9,114
	Karluk Stream	37,105,000	14,842
Northwestern Fisheries Co	Quadra Lake	3,025,750	1,210
	Hetta Lake	8,143,000	3,257
North Pacific Trading and Packing Co	Klawak Lake	3,200,000	1,280
Total		74,258,750	29,703

In addition to the private salmon hatcheries the United States Bureau of Fisheries during the same period operated two hatcheries—one at Afognak, in central Alaska, and the other on Yes Lake, in

southeast Alaska—and planted salmon fry as follows: From Afognak, 39,325,870 red salmon fry and 10,000 humpback salmon fry; from Yes Lake, 48,653,000 red salmon fry and 9,900 coho fry; a total of 87,998,770 fry for both hatcheries.

OBSERVATIONS ON WOOD RIVER.

THE ORDER CLOSING WOOD AND NUSHAGAK RIVERS.

The order of December 19, 1907, closing Wood and Nushagak rivers, in western Alaska, to commercial fishing was strictly enforced during the two past seasons, and no trap was operated or other form of fishing carried on in either river. There were 10 fish traps in operation on the bay during the whole or a part of the season just past, but 2 of these had very small takes. This number is 1 trap fewer than in 1908.

It is plain that the great variation from year to year in the proportion of the annual run taken by the fishermen is unfavorable to uniformity in the run and that the lesser runs are much more heavily fished than the greater, a condition which in the Nushagak region certainly tends to overfishing. The order closing the rivers provides a partial check on overfishing and is especially useful in seasons of small runs. During the season of 1908 it had no effect in limiting the catch, since the packers had little difficulty in completely filling their packs from the fishing in the bay. In 1909, however, the run was much smaller, and not all the canneries completed their packs. Had traps been permitted in the rivers they would have secured a large number of the relatively few fish which, as it was, succeeded in escaping to the spawning grounds by way of Wood River. When runs occur large enough to fill readily the whole pack provided for by the cannery men, the order has no restrictive influence on the catch, but is not oppressive, since at somewhat greater trouble all the fish necessary may be obtained from the bay.

Under the present system of fishing the order is a necessary protection to the fisheries, and is a wise exercise of the power conferred by the Alaska fisheries law.

COUNT OF THE BREEDING RUN IN WOOD RIVER.

The counting investigations begun in 1908 were continued on substantially the same basis during the season of 1909. A rack was placed across the foot of Lake Aleknagik and an actual tally was made at the three gates provided for the purpose of all red salmon entering the lake during the season. The total run into the lake fell far short of the preceding season, being 893,000, as against 2,600,000 in 1908.

The first visit to the lake was made June 7, when from an examination near its foot it appeared to be clear of ice, whereas on May 31, 1908, it was still almost entirely covered. The work of installing the rack was begun June 17 and the temporary crew was taken away on the 22d. The rack was not made entirely tight until the 2d of July. The few salmon first appearing, however, show no tendency to seek the apertures under the chain at the bottom of the web, but find their way readily through the gates. The same or greater trouble was encountered with the floating drift as in the previous season. This drift is composed of dead leaves, grass, twigs, and small limbs of trees set afloat from the shore by the rise of the lake and brought down by the current and favorable winds. It arrived at the salmon rack in greatest abundance between June 26 and July 2, and during this period strenuous exertions on the part of the crew were necessary to keep the web sufficiently clear to relieve the pressure against the piles. As it was, several of these were bent over and had to be held by guy lines. The drift gradually lessened in amount and finally disappeared almost entirely.

The first tally was made June 28 and the last on August 1, the gear being taken out the next day. In 1908, with a large run and the necessity of developing methods of making a proper and at the same time rapid approximation of the numbers, it was thought necessary to estimate from the frequent and regular tally of a uniformly flowing stream of fish. During the present season no estimates of any sort were made. The much smaller run and the fact that three gates were available made an exact count a comparatively easy task. To a certain degree this year's figures corroborate the count of the preceding season, for the daily quotas during the height of the run are consistent with each other during the two seasons, and it was obvious by mere inspection of the daily abundance about the gates that the 1909 run did not approach that of 1908. It is probably possible to make an actual tally in any season, even of the largest runs. The salmon may be held below the rack without injury for a time, and by increasing the number of tally gates the fish may be delivered more rapidly. It is merely a question of a sufficiently strong and tight barricade, with plenty of gates and tallymen.

An interesting coincidence is seen in the fact that the highest daily tally, the crisis or height of the run, occurred on the same day of the month, July 14, in each of the two seasons. While this height of the run will probably be found to occur usually near the middle of July at the lake with as much regularity as the entrance of the run into the bay, which usually occurs about the first of July, it is not to be expected to recur continually on any given date. It is suggestive,

however, to compare this height of the salmon run with the so-called "height of the season" among the fur-seal rookeries on the Pribilof Islands, which occurs about the same time, marking the high tide in the rookery life of the season.

There were two well-recognized runs on the bay, the first occurring July 3 and the second July 11. In each case the run was heavy for the time being, but dwindled rapidly, leaving the canneries after a few days of good fishing to "scrape" for the rest of the season. The daily tally at the salmon rack shows that these two runs remained distinctly separate when the fish reached the lake. Stragglers only were passing the rack up to July 5, and on that date the first run in force arrived at the lake. This run, though falling rapidly, lasted three days. After an interval during which few fish arrived, the vanguard of the second run reached the lake late on the 12th and was in full force on the 13th. It lasted about a week, subsiding more slowly and gradually than the first run. In each case the run passed from the lower bay to the lake within two days, while in 1908 it is certain that from six to nine days were consumed by the head of the main run in making the same trip.

DAILY TALLY OF REDFISH INTO LAKE ALEKNAGIK, ALASKA, DURING THE SEASON OF 1909.

June 28	18	July 17	42,004
June 29	20	July 18	38,050
June 30	425	July 19	17,960
July 1	1,261	July 20	10,826
July 2	809	July 21	8,150
July 3	485	July 22	2,497
July 4	1,583	July 23	3,139
July 5	54,135	July 24	3,000
July 6	43,010	July 25	8,088
July 7	29,319	July 26	4,390
July 8	4,555	July 27	5,193
July 9	3,408	July 28	1,142
July 10	11,340	July 29	395
July 11	586	July 30	39
July 12	28,299	July 31	607
July 13	100,350	August 1	358
July 14	189,610		
July 15	177,002	Total	893,244
July 16	101,191		

Significance of the figures.—The count in Wood River shows an enormous falling off in the spawning run as compared with the preceding season—893,000 as against 2,600,000. The catch of the fishermen on the whole bay likewise fell off, but to no such extent—

4,900,000 as against 6,400,000. The 1909 Wood River run was 34 per cent of the 1908 run; the 1909 Nushagak Bay catch was 76.5 per cent of the 1908 catch.

The relations of the whole redfish runs in Nushagak Bay for the two seasons do not appear so definitely, but it is certain that there was a great falling off. If the catch and the Wood River run—the two accurately known factors—are added together for 1908 and for 1909, the latter is 64 per cent of the former. These totals give in each year the whole run minus the escape up Nushagak, Igushik, and Snake rivers, which has never been counted. The conditions which reduced the run up Wood River apply more or less exactly to the other rivers, and the proportion given may be taken as approximating the size relation of the two annual runs. It may be checked by another method of estimation.

A numerical approximation of the whole 1909 run may be obtained by the method used for the 1908 run and detailed in the 1908 report. Reducing the 1908 maximum and minimum estimates for Nushagak, Igushik, and Snake rivers in the same proportion that the Wood River run has been reduced, adding in each case the Wood River run and the catch on the bay and averaging the two totals, nearly 6,800,000 is obtained as an estimate of the total run of red salmon into Nushagak Bay in 1909. This is 57 per cent of the corresponding 1908 estimate, and thus it is safe to say that the current run was between 57 per cent and 64 per cent of the 1908 run. Of this total of nearly 6,800,000 fish, 85 per cent have been actually counted (Wood River run and the catch), and it is plain that the estimate is not a guess. The 1909 run was not fewer than 6,200,000 and not more than 7,400,000. The escape to the spawning grounds was between 20.5 per cent and 34.3 per cent of the whole run.

If the number escaping to the spawning grounds in 1909 is just sufficient to maintain the run which entered the bay, the rate of increase is between 200 per cent and 400 per cent, depending on which of the extreme estimates, maximum or minimum, is taken as a basis. Considering the relation of take to escape in the past two seasons and the strong presumption of a slowly declining fishery, this 1909 escape is probably insufficient, and 400 per cent is a safe extreme as a possible rate of increase. From the results of the 1908 investigations 100 per cent seems a certain minimum. We may therefore conclude that the Nushagak region during recent years is reproducing red salmon by natural propagation at a rate of increment not lower than 100 per cent nor greater than 400 per cent. In other words, for every salmon reaching the spawning grounds, from two to five return several years later, and of these returning salmon from one to four (the increment)

may be taken by the industry without reducing the productivity. It is to be remembered that these figures represent highly probable extremes and that the present actual rate of increase is somewhere intermediate.

It would be necessary only to count the escape in both Nushagak and Wood rivers for several years to arrive at practically accurate knowledge of the rate of increase for the Nushagak region. The two minor rivers carry so small a part of the total that estimates made from a knowledge of fishing experience in them are entirely sufficient to prevent important error. This rate of increase may, then, be expected to apply without great modification to other red salmon fisheries.

These calculations assume in theory that all the progeny of the spawning grounds of the Nushagak basin, and no others, return as adults to Nushagak Bay. This is not entirely true, for chance and physical conditions probably determine to some extent which individuals and how many shall diverge from their course up Bristol Bay and enter Nushagak Bay instead of continuing to the fisheries at the head of Bristol Bay. There must be some interchange between the several regions of Bristol Bay fisheries. As affecting the determination of the rate of increase this is a difficulty which at present can not be met. It need occasion no anxiety, for it is almost obvious that in the long run regions such as the Nushagak depend on their own spawning grounds for maintenance. The exchange between the fisheries is reciprocal.

Miscellaneous observations.—As in 1908, all species of Pacific salmon were seen at the lake, also several other species of fishes. Salmon other than red salmon were many fewer than during the preceding year and were unimportant in either season. The Dolly Varden trout was also less numerous.

A tally of the salmon showing the twine marks of the gill nets was made on several different days at times of both light and heavy runs. The percentage of twine-marked fish ranged from 2 per cent at the height of the run up to 15.6 per cent on July 19, the last day on which such a count was made. These percentages were somewhat higher in 1908, though the proportion of the run taken was smaller.

One of the most important and impressive differences between the two seasons, observed during the examination of the lake and its creeks and of Wood River, was in the abundance of salmon fry. No one familiar with the waters in both seasons could fail to be impressed by the great increase in the number of small redfish fry—young of that season—during the 1909 summer as compared with the previous one. They were caught in the muddy waters of the upper

bay in May, some with the sac still unabsorbed. They were seen in many places in Wood River. At the native village at the foot of the lake there were swarms of them, and they existed in the lake in various places along its shore, not only off the mouths of creeks but in localities distant from the nearest salmon-carrying creek. In one case they were in numbers on the flats about one of the islands, which they must have reached by crossing deep water, if not spawned directly in the open lake about the island. No such abundance of fry was seen in 1908. The two parent runs of adults readily explain the difference, that of 1907 being unusually small, that of 1908 unusually large, and the corresponding spawning quotas probably even more disproportionate.

The yearlings in their downward migration were frequently seen near shore at the rack, but the chief evidence of their presence was given by the arctic terns, which made almost nightly forays on the passing schools. The web of the salmon rack probably interrupted or delayed the progress of the young salmon, and the terns used the tops of the piles as resting places for observation. They seldom fed much during the day, but were abundantly in evidence late in the evening as the daylight became dimmer.

Compared with the preceding season but few dead fish were found in the vicinity of the rack. The ragged and injured salmon toward the end of the run occurred in about the usual proportion. Bacteriological culture plates were made from the blood of spent salmon after their natural death, but only negative results were obtained. It appears unlikely that the dying spent salmon have uniformly a terminal infection, as has been thought.

The weather during the six weeks ending about August 1 was noteworthy for many bright, warm days. There were no blows as heavy as during the preceding summer. Careful measurements were made to determine the date of seasonal high water in the lake. The highest level was reached June 19, and the fall began within two days. Apparently the water reached about the same level as in 1908. The fall was very slow at first. The rains interrupted the fall, but never occasioned more than a very slight rise during the season. The total fall during the forty-nine days following June 21 was about 41 inches.

THE COD FISHERY.

With one exception, all of the firms and individuals operating in the district for cod exclusively have their headquarters at Seattle, Anacortes, or Tacoma, Wash., and San Francisco, Cal., at which places, or in their immediate vicinity, the kench-cured fish are received and prepared for marketing. Some firms have shore stations located at favorable places in central Alaska, from which the dory fishermen carry on their fishing operations, bringing in the catch daily. These operators also have vessels which engage in fishing on the banks in the North Pacific Ocean and Behring Sea, and are also employed in transporting the kench-cured fish to the curing plants at the home ports.

It has been known for some time that cod were abundant around St. Lawrence Island, in the northern part of Bering Sea, and the Bureau of Education in 1907 seriously considered sending an experienced salter to its station on that island for the purpose of instructing the natives how to cure the fish for the white trade, but for various reasons the project was not carried out. If these cod could be prepared properly, there would be a good demand for them in Nome and St. Michael, both of which are securing their supplies from the Siberian coast at present. One of the best banks around the island is about 10 miles north-northeast from Cape Chibukak.

The commander of the United States revenue cutter *Thetis*, in a letter dated November 19, 1909, reports that he heard of a cod bank "to the westward of Shishmaref Inlet in the Artic Ocean. A former resident of Shishmaref Inlet told me that he had seen large numbers of cod in the vicinity of the hot springs at the head of that inlet in the fall of the year when ice was forming."

Mr. John Nelson, of Squaw Harbor, took up the preparation of stockfish at his new station this year. In curing, the fish are hung over wires, with the skin side up to shed the water and allow the flesh to dry. In the damp climate of Alaska the fish rot when placed with the flesh side up, as has been done heretofore. Only a small quantity of stockfish was prepared, and this was packed in bundles containing 100 fish each, with an average weight of 100 pounds. The packages were wired and burlapped at each end. If the experiment proves profitable, it will be prosecuted more vigorously next year.

SHORE STATIONS.

During 1909 the following shore stations were operated: By the Alaska Codfish Company, at Company Harbor and Moffat Cove, Sannak Island; Unga, Baralof (Squaw Harbor), and Kelley Rock (Winchester), Unga Island; and Dora Harbor, on Unimak Island.

John H. Nelson, at Baralof (Squaw Harbor), on Unga Island. Pacific States Trading Company, at Northwest Harbor, Little Koniuji Island, and Ikatik, on Unimak Island. Seattle-Alaska Fish Company, at Baralof (Squaw Harbor), on Unga Island. Union Fish Company, at Pirate Cove, Popof Island; Northwest Harbor, Little Koniuji Islands; Eagle Harbor and Sanborn Harbor, on Nagai Island; Unga, on Unga Island; Pavlof Harbor and Johnson Harbor, on Sannak Island; and Dora Harbor, on Unimak Island. Some of these stations were operated only during the winter of 1908–9. The Alaska Commercial Company prepared a considerable quantity of codfish at Kodiak.

STATISTICS.

During the year 185 fishermen and 28 shoresmen were employed at the stations, while 54 transporters were employed in operating transporting vessels in Alaska and between the Alaska stations and the California and Washington home stations.

The following tables show the condition of the industry in 1909:

INVESTMENT IN THE CENTRAL ALASKA COD FISHERIES IN 1909.

Items.	Number.	Value.[a]	Items.	Number.	Value.[a]

Total	4,497,958	3,358,764	118,821

VESSEL FISHING.

The following fleet [a] of 14 vessels, with headquarters in California and Washington, operated in Alaskan waters this year, several of them spending the winter of 1908–9 in the North:

[a] None of the data relating to this fleet appears in the statistical tables.

Name.	Class.	Tonnage.	Owner.
Fanny Dutard	Scow	252	J. A. Matheson, Anacortes, Wash.
Harriet G	Brig	188	Do.
Alice	Schooner	220	Robinson Fisheries Co., Anacortes, Wash.
Joseph Russ	do	235	Do.
Maid of Orleans	do	171	Seattle-Alaska Fish Co., Seattle, Wash.
Harold Blekum	do	185	King & Winge, Seattle, Wash.
Vega	do	233	Do.
Fortuna	do	138	Blom Codfish Co., Tacoma, Wash.
Czarina	do	218	Union Fish Co., San Francisco, Cal.
Ottillie Fjord	do	247	Do.
Stanley	do	253	Do.
City of Papeete	Barkentine	370	Alaska Codfish Co., San Francisco, Cal.
John D. Spreckles	Schooner	253	Do.
W. H. Dimond	do	376	Do.

The only change from last year was the dropping out of the *Ivy* (135 tons), which had been chartered by the Union Fish Company during 1908. Most of the fleet met with excellent luck this year and found fish so plentiful that some of them returned several weeks earlier than usual. The schooner *Joseph Russ* made the record catch, bringing home 204,155 fish, all of which were taken, dressed, and salted in fifty-eight days.

While fishing from their dories in Unimak Pass, six of the crew of the *Harriet G* were caught in a sudden blow and driven on the rocks and drowned before they could reach the shore. Two other men who were with the party were saved by a United States light-house tender, which later delivered them aboard their vessel.

Early in the summer the schooner *Czarina*, while fishing in Bering Sea, was blown ashore and for ten days remained on a sand spit. She sustained but slight damage, however.

The vessels from Washington operating in Alaska waters caught 1,147,605 fish, while those from San Francisco caught 520,000, a total of 1,667,605.

In 1908 a fleet of three San Francisco vessels operated in the Okhotsk Sea and caught 445,000 fish. This year but one vessel, the barkentine *Fremont* (328 tons), owned by the Union Fish Company, of San Francisco, visited these grounds. She returned with a catch of 80,000 fish. Her captain reported a large fleet of Japanese vessels fishing there for cod.

THE HALIBUT FISHERY.

The season of 1908 was fairly good, and would have been much better had it not been for the scarcity of bait during portions of the best of the fishing season. For days at a time during the winter vessels had to tie up owing to the impossibility of securing either fresh or salted bait. The question of bait supply has been treated of more fully under the herring fishery.

A NEW FREEZING PLANT AT KETCHIKAN.

The most important and interesting event in the halibut industry this year was the opening in September of the plant of the New England Fish Company at Ketchikan, the finest freezing and cold-storage plant on the Pacific coast. Late in the fall announcement was made that the company's plant at Vancouver, British Columbia, and its two Canadian vessels had been sold to the Canadian Fishing Company (Limited), of Vancouver.

Since the New England Fish Company first began operating on this coast it has had its headquarters at Vancouver, where it outfitted its vessels and prepared their catches for shipment in bond, free of duty, to markets in this country. It operated three vessels with American register and two with Canadian register, the catches of the latter being marketed mainly in Canada, or, when shipped to the United States, paying the regular duty. For several years there has been developing in Canada, and more particularly in British Columbia, a decided opposition to the company, the claim being that it had no rights in British Columbia waters and was deriving a profit that should go to Canadian fishing enterprises. The knowledge of this feeling on the part of the Canadians, and the probability that it would eventually crystallize into some official action, doubtless had considerable weight in the company's decision to establish its plant at Ketchikan.

Other factors influencing the company, and probably the controlling, were (1) the nearness of Ketchikan to the fishing banks, thus enabling the vessels to visit the banks and return in less than one-fourth the time heretofore consumed when Vancouver was the headquarters, and delivering the fish in much fresher condition; (2) the probable opening, in two or three years, of the transcontinental line of the Grand Trunk Railway to Prince Rupert, British Columbia, a port but 92 miles from Ketchikan, by means of which shipments can be made in bond to eastern United States markets in the same time required to cover the distance from Vancouver, the Pacific terminus of the Canadian Pacific Railway, thus saving the coastal run from Dixon Entrance to Vancouver, a distance of 475 miles; and (3) the opportunity to handle the catches made by the large fleet of power and sail vessels and launches during the fall, winter, and early spring months on the banks in the sheltered waters of southeast Alaska.

The site of the new plant in Alaska is at a point on Tongass Narrows about one-half mile from the center of the town of Ketchikan, and this has been named Belanna. The location is on deep water, thus permitting vessels to tie up at the dock at any stage of water.

Work was begun on the buildings in 1908 and was pushed forward as rapidly as the weather would permit.

There are six buildings in the plant at Belanna and three at the power station on George Inlet. The main building at the former place, containing the freezers and storage rooms, is 85 feet by 95 feet and two stories high. The receiving house is 60 by 70 feet and also two stories high. The ice plant is one story in height and 72 by 25 feet, while the power house is 40 by 50 feet. In the rear is a commodious office building. All the working buildings are of wooden construction of the heavy joisted type. The outside surface is covered with vertical matched sheathing with battens over the joists, while all floors, partitions, and walls are insulated with sheet cork with wood insertion and nailed direct to the boarding or joists. It is estimated that the whole plant cost $250,000.

Inclosing a section of the wharf and located in the foreground in close proximity to the freezer is the receiving house, in which the fish are to be washed and dressed in their transit from the vessels to the freezer. After washing and cleaning they are sent to the freezer building, a short distance in the rear. Here there are four freezers each 25 feet by 10 feet 6 inches, in which a temperature of from 25° to 30° F. below zero can be maintained if desired, although it is probable that a temperature of not more than 10° below zero will be required. All freezing is by direct expansion, and each freezer is piped with about 2 feet of 1¼-inch pipe per cubic foot of freezing space. The bunkers in the freezers are in pairs, each nine pipes wide, spaced on 5-inch centers, and nine tiers high, spaced 10 inches apart. This leaves a 3½-foot passage through the center of each freezer opposite the 3½ by 6½ foot serving doors. The large halibut, owing to their size, are placed directly on the tiers of pipes instead of in pans, as is the custom with the smaller fish.

After freezing, the fish are passed through openings in the rear of the freezers into the glazing room, where, after glazing, they are crated and trucked into the storage rooms in the rear half of the first story and the entire second story. It is estimated that the six storage rooms have a capacity of 1,500 tons of fish. The storage and glazing rooms are piped with 1 linear foot of 2-inch pipe per 10 cubic feet of space. The storage rooms will have a temperature of 10 degrees above zero.

The fish are raised to the second-story storage rooms by a 2-ton electric elevator. Shipments of boxed fish are made from the second floor down an incline to the wharf level.

For the purpose of developing power for the plant a 15-foot dam was constructed at the outlet of Lake Whitman, a small lake just inside George Inlet. From here a 36-inch pipe line taps the lake

at a depth of 15 feet in order to get the coolest water and so that no trouble shall be experienced with driftwood or ice. The pipe line is about 3,300 feet in length and enters the power house on a small bay on the inlet. Here a three-phase system of two generators has been installed, each developing 1,000 horsepower. A right of way between the power house and the plant at Ketchikan was cleared and over this was constructed the transmission line of a little less than 5 miles in length.

To protect the buildings from fire, a 500-gallon fire pump has been installed, which has an 8-inch suction from the harbor and discharges into a 6-inch main inclosing the entire group of buildings. From this main seven two-way hydrants are supplied, these hydrants being so located and equipped with fire hose, etc., located in the house inclosing them, that all points may be reached and supplied.

A special pipe connects the plant with the waterworks of the Ketchikan Light and Power Company, this furnishing all the fresh water required for the use of the employees and the operation of the plant.

In the wing adjoining the freezer building is a 20-ton can ice plant, and there is storage space in the rear of this wing for 70 tons of ice. The plant comprises 155 cans of 400-pounds capacity, each arranged in a single battery and served by a 2-ton electric crane. The ice dump discharges the cakes of ice through openings into an air lock at a level 5 feet above the storage floor, from which it is chuted to all parts of the storeroom and packed.

The engine plant is in a separate building and receives the electric current from the power station at George Inlet in a volume of 6,600 volts. With its transformers it reduces that to 440 and 110 and supplies energy to two 150-horsepower motors which operate two 65-ton compressors to force ammonia through the condensers for making ice.

STATISTICS.

During 1909 there were 281 persons employed in all branches of the halibut industry. The reason for the apparently small number recorded for a fishery of such importance is that many of them spend more time in fishing for king salmon than for halibut, and have been counted in the former fishery, where the greater results were accomplished. The number of steamers and launches increased four over 1908. The total investment is almost exactly the same as in 1908. While the catch in 1909 decreased 472,082 pounds as compared with 1908, the value of the catch increased $20,987.

PRODUCTS OF THE SOUTHEAST ALASKA HALIBUT FISHERIES IN 1909.

Products.	Round weight.	Dressed weight.	Value.
Vessel catch:	*Pounds.*	*Pounds.*	
Halibut, fresh	4,425,223	3,540,659	$162,607
Halibut, frozen	240,604	229,050	14,436
Halibut, detched	113,997	85,498	4,132
Total	4,779,824	3,855,207	181,175
Shore catch:			
Halibut, fresh	410,100	328,400	14,354
Grand total	5,189,924	4,183,607	195,529

It is probable that the Bureau of Fisheries steamer *Albatross* will this coming summer make an investigation in the open waters adjacent to southeast and central Alaska, in order to determine whether there are any halibut banks of sufficient importance to justify fishing them. What little investigation has been made heretofore has shown that halibut occur in abundance in the ocean off Chichagof and Baranof islands and the mainland between Cape Spencer and Yakutat Bay, in southeast Alaska, and it is possible they are in greater abundance elsewhere in Alaska waters.

PUGET SOUND FISHING FLEET.

A fleet of Puget Sound power and sail vessels visits southeast Alaska during the months from October to March, when, owing to stormy weather and a scarcity of fish, it is not safe nor profitable to visit the fishing banks near the home ports. This fleet makes its headquarters mainly at Petersburg, at the head of Wrangell Narrows, shipping the catch home from Scow Bay, near by, via the regular steamship lines. The opening in September at Ketchikan of the new plant of the New England Fish Company drew some of the vessels to that town. During the year the fleet caught and shipped 2,259,529 pounds of halibut, valued at $78,920. A few of the Puget Sound fleet of steamers also fish at times in Alaska waters, but it has been found impossible to secure accurate data as to their catches taken in this region. None of the above data are included in the statistical tables of this report.

THE HERRING FISHERY.

The run of herring in southeast Alaska was fairly good during a part of the year. Nothing was done in central Alaska in the curing of herring, the plant on Simeonof Island not being operated for reasons stated at length in the 1908 report. According to trustworthy information herring are quite abundant in Port Clarence, and some fishermen located at Grantley Harbor, near the head of this bay, have been salting on a small scale during the past two or three years and selling the fish at Nome and the various settlements in that section of Alaska.

During the summer herring are frequently found around the salmon cannery at Petersburg, and on several occasions the assistant agent caught a number with hook baited with salmon eggs, the fish taking the bait very eagerly. When opened their stomachs were found to be full of salmon eggs.

HERRING FOR BAIT.

In the fall of 1908 one of the floating salmon traps, which had been fitted with a herring spiller composed of 1½-inch mesh, was set in Tongass Narrows for the purpose of catching herring for bait. It met with very poor success, however.

Herring is the bait almost universally employed in the halibut fishery of Alaska, but the supply has not kept pace with the demand. The question of a constant and abundant supply of bait is, in fact, the most serious problem confronting the halibut fishermen. At times the herring will appear in large numbers in the bays and sounds of southeast Alaska, but they are not in much demand until

halibut fishing begins, about September 15. At present most of the herring for food and bait is taken between August 1 and May 1, the fish being the rest of the year in the deep waters or having their stomachs filled with a red feed which burns them out very shortly after death, thus seriously affecting their value and usefulness as either bait or food.

The establishment of several small freezers at places close to the halibut banks, where herring could be frozen and stored until needed in winter, when they are usually very scarce, would probably solve the problem of a constant and abundant supply of bait. Salmon backs could also be frozen and would undoubtedly make excellent bait for halibut. It is probable that the New England Fish Company will devote part of its facilities to the freezing of bait for halibut fishing, while there are several other propositions in this line under consideration at present in other towns in southeast Alaska.

During the past summer the Canadian authorities issued an order in council prohibiting American fishing vessels from buying bait in British Columbia ports. Heretofore the halibut vessels operating in Dixon Entrance and Hecate Straits have been in the habit of purchasing their bait in Nanaimo, British Columbia, while on their way north, but this order compelled them to look elsewhere, and several of them visited southeast Alaska for the purpose. It is highly probable that more of them will do so each season if they can be assured of being able to get the bait when they come.

THE FERTILIZER QUESTION.

The scarcity of bait has again brought to the fore the question whether fertilizer plants should be permitted to utilize herring and other food fishes in their work. The present fisheries law does not prohibit such use of food fishes, and there is now one plant—that of the Alaska Oil and Guano Company, at Killisnoo, in southeast Alaska—engaged in the industry. The company gives employment to a number of the inhabitants of the town of Killisnoo, an Indian settlement, and each year between June and October disburses about $40,000 in wages to these natives and to the white employees. The plant is worth about $35,000. In 1909 it used 52,000 barrels of herring and 3,846 barrels of salmon (dog and humpback) in the preparation of fertilizer and oil. Two steamers, with purse seines, do the fishing. The fishermen complain that the use of these nets in the bays and sounds breaks up the schools, and that the quantity taken has been so large that the schools have suffered seriously in number and size. In justification of its use of herring and certain species of salmon the company has always made the plea that these

fishes were not being used for food and could not be so prepared profitably.

There is insufficient justification in the company's plea now, although it was partially true as regards herring and dog salmon for some years subsequent to 1882, when the plant was first established. Humpback salmon form the major part of the pack at the southeast Alaska canneries, while dog salmon are being used in greater numbers each year. As to herring, the statistics of the fishery shown in this and former reports are ample evidence of the economic uses to which they can be put other than in the preparation of fertilizer and oil.

In view, therefore, of the great need of the herring for food and bait, the time has arrived when the use of food fishes in the preparation of fertilizer should be prohibited. In justice to the company in question, however, at least one full season should be allowed in which to readjust operations and prepare for the change. It is possible that this plant might be profitably operated with the offal from the canneries in its neighborhood, and thus prevent, in part at least, the enormous waste which annually occurs when the offal is thrown overboard and allowed to pollute the waters adjacent to the canneries.

Another reason for saving the herring is that they constitute food for many other fishes. The principal food of the king salmon is herring, and as the catching of king salmon by trolling now forms one of the most important and profitable of the fisheries of southeast Alaska, no condition that adversely affects it should be permitted to exist. There is little question that the serious depletion of the herring schools would correspondingly impair the abundance of king salmon.

MISCELLANEOUS FISHES, CRUSTACEA, SHELLFISH, ETC.

Eulachon (*Thaleichthys pacificus*).—An enormous run of this fish was reported by prospectors to have appeared in the Sushitna River, one of the tributaries of Cook Inlet, the first week in June. It is also abundant in a few other streams in southeast and central Alaska for some two weeks in the spring. Few are used as food by the whites, but the natives consume large quantities.

Sturgeon.—A sturgeon 3 feet 10 inches in length is reported to have been caught in a gill net operated near the mouth of the Stikine River.

A natural history collector of Wrangell reports having seen a sturgeon in the shallow waters of Union Bay in June, 1901. It was about 5 feet in length.

Crabs.—Crabs are exceedingly abundant, particularly in southeast Alaska and in Prince William Sound, in central Alaska, and have

been reported in varying abundance from nearly every section. Recent information is to the effect that edible crabs of a fine variety are caught around King Island, a small island in Bering Strait.

Heretofore the catching and marketing of crabs has been carried on in a desultory fashion at a few places in southeast Alaska and in Prince William Sound, but none were shipped out of the district. This summer one of the Puget Sound dealers, whose sales had been considerably curtailed owing to the inadequacy of the supply from Washington waters and the close season which prevails part of the year, visited Wrangell, Ketchikan, and Juneau, in southeast Alaska, and interested the local dealers and fishermen in the business to the extent that several of them took it up.

The crab pots are of varying sizes and shapes. At Wrangell a rectangular pot of wooden framework is used, about 40 inches long, 18 inches high, and 30 inches wide, with 3½-inch stretch mesh net covering. The tunnels, of which there is one at each end, are 7 inches in width and 5 inches in height. At Ketchikan a circular pot is used, about 3 feet in diameter and 18 inches in height, with two opposite tunnels. The Juneau crab men use a pot similar to the Wrangell variety. These pots cost the fishermen about $1.25 each.

The pots are set on trawls, about 25 or 30 to a trawl. Each is attached to a gangion about 5 fathoms long, thus permitting the raising and emptying of the pot without bringing up the trawl itself. The trawls are marked by buoys and held by anchors. On some of the trawls baited hooks are placed between the gangions for the purpose of catching bait for the pots. All sorts of fish, clams, etc., are used as bait.

Crabs from 6 inches up in size are utilized for shipping. The shippers classify them by weight and size as follows: Medium average, 1½ pounds; large average, 2½ pounds; large, 2½ to 3½ pounds. The fishermen in the Wrangell district received 75 cents per dozen for 6-inch crabs (which average from 1½ to 2 pounds each), and $1.10 per dozen for 6½-inch and larger crabs. The crabs are measured the broad way of the back. The freight to Seattle is $7.50 per measured ton, which would include 35 dozens of crabs. If placed in the cold-storage compartments the rate is $15 per ton. The crabs are packed in wooden boxes holding about 15½ dozens each. At first all were shipped alive, packed in seaweed, but so many died on the way or arrived in bad condition that finally all were boiled before being shipped. These arrived on Puget Sound in excellent condition. A large number were also marketed locally, while a few were shipped to points in the Northwest Territory along the line of the White Pass Railway.

Shrimps.—Shrimps are found in a number of places in southeast Alaska, being fairly abundant at times in Lynn Canal and in the vicinity of Wrangell, while the investigations of the *Albatross* have shown that they are abundant in the waters of central Alaska, south of the Alaska Peninsula. They have been reported from a few places in western Alaska. This summer the assistant fur-seal agent on St. George Island found about a pint of shrimps, *Spirontocaris polaris* (Sabine) in the stomach of a nesting cormorant killed on the island. The condition of the shrimps when taken from the bird's stomach indicated that they had but recently been eaten, thus showing that the crustacean must be abundant in that section of Bering Sea.

Preparations are now under way at Wrangell, in southeast Alaska, for the catching and shipping of shrimps to Puget Sound ports, where they command high prices. Some prospecting has already been done and a few of these crustaceans, known to the fishermen of Puget Sound as "big-spots" (which average 5 inches in length), "coon-stripes" (2 inches in length), and "pinks" (1 to 1½ inches in length), have been gathered. For this purpose a trawl is used which has an oblong mouth 10 feet long by 4 feet wide, the net bag being about 10 feet in length. The mouth framework is made of iron pipe. The trawl is dragged from the stern of the boat and is hauled in by means of a windlass.

Clams.—Clams are abundant throughout Alaska, but in no section are they used to any considerable extent commercially, although the time is probably not far distant when the gathering and marketing of clams will be an important industry. The razor clam, *Machæra patula*, is especially abundant in southeast and central Alaska. The mud clam (probably *Panopea generosa*) has been reported from southeast Alaska. There are said to be large beds of clams and other edible shellfish along the Arctic coast, especially between Cape Prince of Wales and Icy Cape, immense numbers being washed up on the beaches during the prevalence of heavy southerly and southwesterly gales.

Cockles.—Beds of cockles, sometimes called scallops, are known to exist in Funter Bay, on Admiralty Island, and in Dry Strait, near Wrangell, and would probably be found in many other places if systematic search were made. They are eaten, but not sold.

Mussels.—Mussels are plentiful in many sections, especially along the Aleutian chain and in southeast Alaska, where they form an occasional addition to the natives' larder. About twenty years ago some were taken from the neighborhood of Unalaska and planted around St. Paul and St. George islands, of the Pribilof group, where they have thrived and are now found in abundance. The few whites

living on the islands eat them after steaming them in the shell, and report them as delicious.

Oyster.—A native rock oyster has been reported from Sitka, Peril Straits, and the Skookum Chuck on the west side of Prince of Wales Island, in southeast Alaska, and Latouche Island, in Prince William Sound, in central Alaska.

Abalone.—The abalone is found along the ocean side of the islands in southeast Alaska, but no use is made of it.

Octopi.—Octopi are abundant in many sections and are eaten by the natives. A few of the crab fishermen of Wrangell expect next year to engage in the business of catching them with spear and hook and line baited with fish heads, clams, etc. They bring from 6 to 14 cents per pound in the Seattle markets.

Chiton.—A chiton (*Katherina tunicata* Wood), known locally as the "gum boot," is found in southeast Alaska waters (observation would probably disclose that it is a resident of other sections of Alaska), where it is gathered and eaten by the natives.

Sea urchin.—The sea urchin is very abundant along the Aleutian chain, and large numbers are consumed by the natives.

Holothurians.—Bêche-de-mer, trepang, or sea cucumbers, as they are known to the trade, are very abundant in southeast Alaska, but absolutely no use is made of them at present. They are especially abundant in the shallow water in May and June. It is probable that nothing will be done with this product in Alaska until the supply from the South Seas falls off.

Algæ.—In April and May the Thlingits and Yakutats, and possibly other tribes, gather an alga or seaweed (probably *Porphyra laciniata*) which they dry, press in boxes, and put away to be eaten later. In May the Kake tribe gather algæ, and mixing it, when moist, with salt, compress it into cakes a foot square, and from one-fourth to one-half inch in thickness. In this condition it will keep for some time. The prepared product is used in making soups and for other culinary purposes. A small trade in these cakes is carried on with other villages. Certain species of algæ are very nutritious, and it is probable that when their good qualities become better known the whites will seek them as a food product.

THE WHALE FISHERY

The whaling station of the Tyee Company, at Tyee, at the lower end of Admiralty Island, in southeast Alaska, which is the only shore whaling station in the United States where all parts of a whale are utilized, was operated more vigorously than ever this year. In addition to the steamer *Tyee jr.*, which was used in 1908, the gasoline

schooner *Lizzie S. Sorrenson* (49 net tons) was fitted up and used as a whaler, the gasoline schooner *Prosper* being used, as in 1908, for towing the whales to the station. The first whale was killed on May 7. Part of the whaling products from this station shown in the statistical tables are from whales killed in 1908, the products not being shipped until 1909.

There are shore whaling stations along the Arctic shores of Alaska at Point Hope, Cape Lisburne, Icy Cape, and Point Barrow. There are but few white men at these stations, Eskimos composing the most part of the boat crews. Whales are hunted in the open leads in the ocean offshore from the stations. As a rule, only the bone is saved, although the natives use a considerable quantity of the blubber and meat as food. Owing to the difficulty of communicating with these points, no data relating to the persons employed and the investment have been secured. The bone shipped out is shown in the statistical tables.

The latest reports from these stations are that Point Barrow secured 11 whales and Point Hope 13 whales, a decrease of 12 from last year, while at Icy Cape, where 10 or 12 whales were killed in 1908, only 400 pounds of poor bone was secured this year.

Owing to the fact that the big catch of bone by the various fleets in 1908 had glutted the market, the owners of the Arctic fleet are reported to have agreed to hold whalebone at $5 per pound, and not to send their vessels to the Arctic this year, in order to give the whalebone market an opportunity to absorb the surplus supply. Early in the season the owners of one steamer quietly outfitted her and sent her north. Not to be outdone, most of the other owners also outfitted and sent north a few of their vessels. The fleet comprised the steamer *Herman* (290 tons), the steamer *Jeanette* (240 tons), the steamer *Karluk* (221 tons), which will spend the winter of 1909–10 in the North; and the schooner *Rosie H.* (69 tons), which spent the winter of 1908–9 in the North, and was still there when this report closed, although an unconfirmed report had been received to the effect that she was ashore near Flaxman Island. The data relating to this fleet do not appear in the statistical tables of this report, as the headquarters are in San Francisco.

AQUATIC FURS.

Beaver.—But few beavers are now coming from the Yukon Valley, at one time the principal source of supply, the greater part of the present meager quantity coming from the Kuskokwim River. The catch was 2,323 skins, an increase of 1,043 skins over 1908, when 1,280 were taken.

Muskrat.—This animal appears to be increasing in numbers in the Yukon Valley. The natives use many of the skins in barter with other tribes, the greater part being made into clothing, blankets, or robes. Some of the others are made into small articles to be sold to tourists. The outside demand for Alaska muskrat is increasing each year. This year's shipments comprised 121,568 skins, an increase of 89,856 skins over 1908, when only 31,712 were shipped.

Land otter.—There has been a small increase in the catch of land otter, 1,333 having been taken in 1908, while 1,493 were taken in 1909, a gain of 160.

Sea otter.—But one vessel, the schooner *Everett Hays*, owned by Mr. Samuel Applegate, of Unalaska, fitted out for sea-otter hunting in 1909. She hunted from May 16 to August 27 and had very rough weather. Her catch was 17 skins, all of which were secured in portions of six days, covering a period from July 10 to 26.

The Atka natives secured 4 skins near Tanaga Island, in the Aleutian chain. Mr. Charles Rosenberg, who patrols a stretch of some 30 miles of beach on the Bering Sea side of Unimak Island on the lookout for the washing ashore of dead sea otter, secured none this year.

In addition to the catch shown above, 16 skins were secured in various ways and places and shipped out of Alaska, making a total of 37 skins in all, an increase of 5 over 1908.

The British Columbia pelagic sealing fleet, which has been devoting considerable attention of late to sea-otter hunting off the Alaska coast, secured 18 skins this year, and it is very probable that the Japanese pelagic sealing fleet also secured a few skins, although there has been no report received as to the number taken.

Fur seal.—This year 397 fur-seal skins were taken by the Indians in southeast Alaska and sold at a price aggregating $7,383 (price paid the hunters and not the London price). These skins, with the 14,368 shipped from the Pribilof Islands, make a total of 14,765 fur-seal skins shipped from Alaska in 1909.

Outside of the Pribilof Islands, Sitka is the only place on the Pacific coast of the United States from which fur-sealing operations of any consequence are carried on. Under the law, seal hunting is restricted to Indians, white citizens not being permitted to engage in it.

The only time that the herd visits the neighborhood of Sitka is in April and May, when on its way to the Pribilof Islands, in Bering Sea, to breed. About the middle of April the Indian hunters, with their families, leave for the hunting grounds and establish their camps on Tava, Wrangell, and Biorka islands, small islands a few miles from Sitka. This year 18 boat parties had their headquarters on Tava Island, 7 on Wrangell Island, and 9 on Biorka Island. Each

boat party is composed of from 3 to 5 men, and these use sailboats costing about $130 each. Repeating shotguns, costing from $25 to $35 each, are the only weapons used. The hunting is done in the open ocean, and the boats from the various camps cover an area of from 35 to 50 miles directly out from shore and about the same distance up and down the coast. Good weather is essential, and this year the sealers were very fortunate, but few storms occurring during the season.

The hunters on Tava Island secured 215 skins, those on Wrangell Island 84 skins, while those on Biorka Island secured 97 skins, a total of 396 skins. The largest number of skins secured by any one boat was 30, this boat having its headquarters on Biorka Island. One boat operating from the same island secured no skins at all, while another from Wrangell Island killed but one seal. The average per boat was about 11½ skins. The proportion of female skins to the total number killed was reported to be about 1 in 6.

In outfitting these boats, the hunter, who is head man, furnishes the boat and gun, while the rowers furnish the ammunition and food. The gross proceeds arising from the sale of the skins taken are divided equally among the crew, with the exception of the hunter, who gets $3 or $4 more than the others.

Upon the return to Sitka a committee of two is appointed to supervise the sale of the skins. Late in May the buyers from the States appear in Sitka, and as soon as possible thereafter the date of the sale is fixed, usually for some day between June 1 and 5. On this day the skins are all brought to one house, where they are sorted into three sizes—"small," "medium," and "large"—care being taken to keep each boat's catch separate from the others. The "small" skins are those of the pups born during the previous two years. The "medium" skins are said to have the best fur, but the buyers prefer the "large" ones on account of their size. Large skins were a little more numerous this year than the medium skins. The buyers are not allowed to pick out the choice skins and bid on these alone, but must take them as they run, the subdivision in the beginning being made merely in order that the buyers might see what they were bidding on.

Only two nonresident buyers were present at the sale this year. The best price offered was $20 per skin, but the Indians refused to sell for less than $25 per skin, the price received in 1908, and as a result the sale was declared off. Later on the skins were disposed of at private sale to local buyers, who paid $17 each for all but a few which brought $20 each.

These skins are usually much sought after by the dealers, because, being taken by natives, and a certificate from the collector of customs to this effect being attached to each, they can, under the law, be

sent abroad to be cleaned and dyed and brought back to be sold in our markets. The possession of such a certificate is considered to add about $10 to the value of the skin.

The pelagic fleet hailing from British Columbia and working on the northern herd was composed of 5 vessels, and its catch is reported to have been 3,555 skins. The Japanese fleet working on the Alaska herd consisted of 23 vessels and is reported to have secured about 10,000 skins. The Indian canoe catch along the British Columbia coast while the herd was migrating northward amounted to 187 skins.

A Canadian pelagic sealing schooner, alleged to have been the *Pescawha*, of Victoria, visited Chirikof Island, a small island southwest of Kodiak Island, on June 12, and two boat loads of armed men landed and killed 5 cattle, taking the carcasses aboard the schooner. Protests from a native who was in charge of the cattle for the owner, and even went aboard the vessel to remonstrate with the master regarding the raid, were disregarded.

This outrage recalls an occurrence in 1907, when the native village of Uguiak, a few miles inside the mouth of Alitak Bay, at the south end of Kadiak Island, was raided by the crew of a Japanese sealing schooner. Throughout central Alaska there are a number of such small native villages, which are practically deserted during the summer months, when the inhabitants are working for the salmon canneries and salteries, in some instances 40 or 50 miles away. The safety of these villages is a matter of vital interest not only to the natives but to cannery and saltery proprietors as well, who draw upon them for labor. At the present time, however, there is practically no coast patrol or other protection in this region of central Alaska.

Upon the sworn complaint of several Sitka Indian sealers that Japanese sealing vessels were killing seals within the 3-mile limit, and also landing on certain islands near by, the deputy marshal at Sitka, accompanied by a detail of marines from the post at that place, went out in launches on May 3 and captured the schooner *Kaise Maru*, of 68.44 tons gross burden and hailing from the port of Ishihama, Japan, which was alleged to have been anchored at the place captured since April 28. The schooner, which was fully equipped for sealing, and had 10 skins aboard, was brought to Sitka, and shortly thereafter her crew of 30 people were transferred to the jail at Juneau, where they were confined until the time of their trial in September. All were acquitted through the inability of the Indian witnesses to fix accurately the distance from shore at which the schooner was working.

Early in May the collector of customs ordered a Japanese sealing schooner, which had been anchored for several days in Yakutat Bay for no apparent reason, to put to sea.

RECOMMENDATIONS.

1. That vessels be provided for use of the salmon inspection service, as recommended in the 1908 report and elsewhere in these pages.

2. That the provisions of chapter 425 of the act of Congress passed March 3, 1899, relating to pollution of the navigable waters of the United States and their tributaries, be extended to protect the Alaskan fisheries, and that the agents of the Department of Commerce and Labor be empowered to enforce them.

3. That no more industrial plants for the packing, preserving, or freezing of salmon in Alaska be allowed to be established except by authorization of the Secretary of Commerce and Labor.

4. That the use of food fishes in the manufacture of fertilizer and oil be forbidden by law, effective after reasonable notice to owners of existing plants.

LAWS AND REGULATIONS RELATIVE TO FUR-SEAL FISHING

Bureau of Fisheries Document No. 732

68427°—11 ——19

LAWS AND REGULATIONS RELATIVE TO FUR-SEAL FISHING.

The following act of Congress, approved December 29, 1897, and the annexed regulations of the Paris Tribunal of Arbitration, concluded at Washington, February 29, 1892, in relation to the fur seals, are published for the information of all concerned:

ACT OF CONGRESS APPROVED DECEMBER 29, 1897.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That no citizen of the United States, nor person owing duty of obedience to the laws or the treaties of the United States, nor any person belonging to or on board of a vessel of the United States, shall kill, capture, or hunt, at any time or in any manner whatever, any fur seal in the waters of the Pacific Ocean north of the thirty-fifth degree of north latitude and including Bering Sea and the Sea of Okhotsk.

SECTION 2. That no citizen of the United States, nor person above described in section one, shall equip, use, or employ, or furnish aid in equipping, using or employing, or furnish supplies to any vessel used or employed, or to be used or employed in carrying on or taking part in said killing, capturing, or hunting of fur seals in said waters, nor shall any vessel of the United States be so used or employed.

SEC. 3. That every person guilty of a violation of the provisions of this Act, or of any regulations made thereunder, shall, for each offense, be fined not less than two hundred dollars or more than two thousand dollars, or imprisoned not more than six months, or both; and every vessel, its tackle, apparel, furniture, and cargo, at any time used or employed in violation of this Act, or of the regulations made thereunder, shall be forfeited to the United States.

SEC. 4. That if any vessel of the United States shall be found within the waters to which this Act applies, having on board fur-seal skins, or bodies of seals, or apparatus or implements suitable for killing or taking seals, it shall be presumed that such vessel was used or employed in the killing of said seals, or that said apparatus or implements were used in violation of this Act until the contrary is proved to the satisfaction of the court.

SEC. 5. That any violation of this Act or of the regulations thereunder may be prosecuted either in the district court of Alaska or in any district court of the United States in California, Oregon, or Washington.

SEC. 6. That this Act shall not interfere with the privileges accorded to Indians dwelling on the coast of the United States under section six

of the act of April sixth, eighteen hundred and ninety-four, but the limitations prescribed in said Act shall remain in full force.

SEC. 7. That this Act shall not affect in any way the killing or taking of fur seals upon the Pribilof Islands, or the laws of the United States relating thereto.

SEC. 8. That any officer of the Naval or Revenue Cutter Service of the United States, and any other officers duly designated by the President, may search any vessel of the United States in port or on the high seas suspected of having violated or of having an intention to violate the provisions of this Act, and may seize such vessel and the offending officers and crew and bring them into the most accessible port of the States and Territory mentioned in section five of this Act for trial.

SEC. 9. That the importation into the United States by any person whatsoever of fur-seal skins taken in the waters mentioned in this Act, whether raw, dressed, dyed, or manufactured, is hereby prohibited, and all such articles imported after this Act shall take effect shall not be permitted to be exported, but shall be seized and destroyed by the proper officers of the United States.

SEC. 10. That the President shall have power to make all necessary regulations to carry this Act into effect.

Approved, December 29, 1897.

Under the provisions of the foregoing act of Congress it is unlawful for any citizen of the United States or any vessel thereof to engage in pelagic sealing *at any time or in any manner*, in the waters of the Pacific Ocean north of the thirty-fifth degree of north latitude, in the Bering Sea, and the Sea of Okhotsk, and it shall be the duty of vessels of the Revenue Cutter Service of the United States to seize any United States vessel found violating this law, *whether during the open or closed season* prescribed in the regulations of the Paris Arbitration Tribunal, and to send or bring such vessel, her officers and crew into the most accessible port of the United States for trial.

REGULATIONS OF THE PARIS TRIBUNAL OF ARBITRATION.

Whereas the following articles of the award of the Tribunal of Arbitration constituted under the treaty concluded at Washington the twenty-ninth of February, eighteen hundred and ninety-two, between the United States of America and Her Majesty the Queen of the United Kingdom of Great Britain and Ireland, were delivered to the agents of the respective Governments on the fifteenth day of August, eighteen hundred and ninety-three:

ARTICLE 1.

The Governments of the United States and Great Britain shall forbid their citizens and subjects, respectively, to kill, capture, or pursue at any time, and in any manner whatever, the animals commonly called fur seals, within a zone of sixty miles around the Pribilof Islands, inclusive of the territorial waters.

The miles mentioned in the preceding paragraph are geographical miles, of sixty to a degree of latitude.

ARTICLE 2.

The two Governments shall forbid their citizens and subjects respectively, to kill, capture, or pursue, in any manner whatever, during the season extending, each year, from the first of May to the thirty-first of July, both inclusive, the fur seals on the high sea, in the part of the Pacific Ocean, inclusive of the Bering Sea, which is situated to the north of the thirty-fifth degree of north latitude, and eastward of the one hundred and eightieth degree of longitude from Greenwich till it strikes the water boundary described in article one of the treaty of eighteen hundred and sixty-seven between the United States and Russia, and following that line up to Bering Straits.

ARTICLE 3.

During the period of time and in the waters in which the fur-seal fishing is allowed, only sailing vessels shall be permitted to carry on or take part in fur-seal fishing operations. They will, however, be at liberty to avail themselves of the use of such canoes or undecked boats, propelled by paddles, oars, or sails, as are in common use as fishing boats.

ARTICLE 4.

Each sailing vessel authorized to fish for fur seals must be provided with a special license issued for that purpose by its Government, and shall be required to carry a distinguishing flag to be prescribed by its Government.

ARTICLE 5.

The masters of the vessels engaged in fur-seal fishing shall enter accurately in their official log book the date and place of each fur-seal fishing operation, and also the number and sex of the seals captured upon each day. These entries shall be communicated by each of the two Governments to the other at the end of the fishing season.

ARTICLE 6.

The use of nets, firearms, and explosives shall be forbidden in the fur-seal fishing. This restriction shall not apply to shotguns when such fishing takes place outside of Bering Sea during the season when it may be lawfully carried on.

ARTICLE 7.

The two Governments shall take measures to control the fitness of the men authorized to engage in fur-seal fishing; these men shall have been proved fit to handle with sufficient skill the weapons by means of which this fishing may be carried on.

ARTICLE 8.

The regulations contained in the preceding articles shall not apply to Indians dwelling on the coast of the territory of the United States or of Great Britain, and carrying on fur-seal fishing in canoes or undecked boats not transported by or used in connection with other

vessels and propelled wholly by paddles, oars, or sails, and manned by not more than five persons each in the way hitherto practiced by the Indians, provided such Indians are not in the employment of other persons and provided that, when so hunting in canoes or undecked boats, they shall not hunt fur seals outside of territorial waters under contract for the delivery of the skins to any person.

This exemption shall not be construed to affect the municipal law of either country, nor shall it extend to the waters of Bering Sea or the waters of the Aleutian Passes.

Nothing herein contained is intended to interfere with the employment of Indians as hunters or otherwise in connection with fur-sealing vessels as heretofore.

ARTICLE 9.

The concurrent regulations hereby determined with a view to the protection and preservation of the fur seals, shall remain in force until they have been, in whole or in part, abolished or modified by common agreement between the Governments of the United States and of Great Britain.

The said concurrent regulations shall be submitted every five years to a new examination, so as to enable both interested Governments to consider whether, in the light of past experience, there is occasion for any modification thereof.

The above regulations of the Paris Tribunal of Arbitration are still in force as applicable to *British vessels*. The closed season for pelagic sealing is therein fixed from the first of May to the thirty-first of July, both inclusive, during which period it is unlawful for British vessels to kill, capture, or pursue the fur seals on the high seas in the Pacific Ocean north of the thirty-fifth degree of north latitude, or eastward of the one hundred and eightieth degree of longitude. Under said regulations British vessels are permitted to engage in pelagic sealing after the thirty-first of July, but in the performance of said sealing they are forbidden to enter within a zone of sixty miles around the Pribilof Islands. It shall be the duty of vessels of the Revenue Cutter Service detailed to patrol the waters above described to seize any British vessel found violating the said regulations of the Paris Arbitration Tribunal, and send or bring the vessel so offending, with all persons on board, together with the proofs and declarations of the officer making the seizure, to Unalaska and deliver her to the senior British naval officer present, or to the most convenient port in British Columbia and there deliver her to the proper authorities of Great Britain or to the commanding officer of any British vessel charged with the enforcement of said regulations.

In addition to the foregoing laws for the protection of fur seals, the President has issued executive orders creating government reservations as follows in the vicinity of the islands of St. Paul and St. George, Alaska, and forbidding the disturbance of all animal life found thereon, under penalties described in the act of Congress approved May 11, 1908:

Walrus and Otter islands, of the Pribilof Group, in Bering Sea, located approximately in latitude 57° north, longitude 170° west from Greenwich; known as the "Pribilof Reservation."

St. Matthew Island, Hall Island, and Pinnacle Islet, in Bering Sea, located approximately in latitude 60°, 30′ north, longitude 172° 30′ west from Greenwich; known as "Bering Sea Reservation."

Bogoslof Islands, Alaska, in Bering Sea, located approximately in latitude 53 degrees 58 minutes north, longitude 167 degrees 53 minutes west from Greenwich, known as the "Bogoslof Reservation."

The act approved June 14, 1906, prohibits aliens from fishing in the waters of Alaska within the jurisdiction of the United States.

CHARLES NAGEL,
Secretary of Commerce and Labor.

INTRODUCTION.

After the purchase of Alaska by the United States in 1867, the Pribilof Islands, which were a part of the purchase and of immense value as one of the breeding grounds of the northern fur seal, were set aside as a government reservation and placed under the administration of the Treasury Department. In 1870, under authority from Congress, the Secretary of the Treasury leased for twenty years to the highest bidder, which was the Alaska Commercial Company, the sole right to take sealskins on these islands. During this period the income to the Government was $6,010,565, representing 1,840,364 sealskins taken by the lessee. In 1890 the contract with the Alaska Commercial Company having expired, the sealing privilege was again leased for twenty years, the highest bidder in this case being the North American Commercial Company. The number of skins taken during this period was 339,180, for which the Government has received $3,752,415. In 1903, with the creation of the Department of Commerce and Labor, the administration of the seal islands was transferred from the Secretary of the Treasury to the Secretary of Commerce and Labor, who, on December 28, 1908, placed their general management under the direct control of the Commissioner of Fisheries.

Under the terms of the contract, which expired May 1, 1910, the lessee paid $10.22½ for each sealskin taken, the Government determining the number and classes of seals that should be killed each year and supervising the killing through its agents stationed on the islands. The company employed the natives to kill the seals, paying them a stated amount per skin, and in addition furnished them, annually, dried salmon, salt and barrels for preservation of the meat supply, 80 tons of coal, comfortable dwellings, schoolhouses, teachers, physicians, and medicines; it furnished also all the necessaries of life to the widows, orphans, and aged and infirm inhabitants. To supplement the natives' earnings, the United States Government appropriated $19,500 each year for their fuel, clothing, and food.

The lessee purchased also, under yearly contract, skins of the arctic foxes, which are found chiefly on the island of St. George. The trapping of these animals and the selection for killing are under direct charge of the government agents. The entire revenue from the foxes ($5 for each blue pelt and $1 for each white) is applied to the support of the natives.

THE FUR-SEAL FISHERIES OF ALASKA IN 1909.

By WALTER I. LEMBKEY,
Agent in Charge.

STATISTICS OF SEALS KILLED.

ST. PAUL ISLAND.

During the lessee's sealing season of 1909, which began June 28 and ended July 31 following, a total of 9,508 sealskins was secured on St. Paul Island. For this there were 35 drives, one of which was made for the additional purpose of securing bachelors for the breeding reservation. For the whole season, the general average of skins obtained in each drive was 271.

During the fall of 1908 and spring of 1909, 7 drives were made on St. Paul Island by the agents to furnish food for the natives. From these, 1,506 skins were secured. This number, together with 32 which had been retained from the previous season and were ordered to be delivered to the lessee by the letter of the Commissioner of Fisheries dated March 11, 1909, and with 7 skins taken from seals killed by the watchmen at Zapadni for food, made a total of 11,053 skins on hand on St. Paul Island on July 31, 1909.

ST. GEORGE ISLAND.

On St. George Island during the lessee's killing season of 1909, which covered the period from June 19 to July 31 of that year, 2,792 seals were killed. This number represents 14 drives, with an average of 199 skins obtained in each drive.

During the fall of 1908 and spring of 1909 (the so-called "food-killing" season), 521 seals were killed for natives' food by watchmen and in drives made by the government agents, and these skins also were delivered to the lessee. There were delivered to the lessee, under the authority previously quoted, 5 sealskins retained by the

government agents from the preceding season because they exceeded the weight allowed by the regulations.

There were on hand, therefore, on St. George Island on July 31, 1909, 3,318 sealskins, gathered from the sources enumerated.

[a] Four skins of this year's catch exceeding the limit of 8½ pounds in weight are retained in salt, subject to future disposition. The number available for shipment the current year is therefore 3,314.

TOTAL SEALSKINS SHIPPED.

From St. Paul Island, on August 14, 1909, on the steamer *Homer*, there were shipped 11,054[a] sealskins, 32 of which were chargeable to the quota of 1908 and 11,022 to that of 1909. From St. George Island there were shipped on the same vessel 3,314 sealskins, all chargeable to the quota of 1909, with the exception of 5 skins credited to 1908 under the authority already quoted.

The total shipment of skins in 1909 from both islands, as detailed in the foregoing, was 14,368, of which 14,331 are credited to the quota of 1909, and 37 to the quota of the previous year, 1908.

OBSERVANCE OF REGULATIONS.

On St. Paul Island the lessee took only 1 skin which failed to weigh at least 5 pounds, and none were taken weighing over 8½ pounds, the limits prescribed by the Department. It is doubtful, furthermore, whether the 1 skin was not the result of an accident in clubbing or was not taken from a seal that had died from overheating during a drive. As the good faith of the lessee was undeniably demonstrated in every particular this 1 skin was permitted to be included in the shipment.

On St. George Island 4 skins exceeding 8½ pounds in weight were taken, and these are now retained in salt on that island awaiting instructions.

WEIGHTS OF SKINS.

In addition to being weighed on the islands the lessee's take of skins in 1909, when shipped to London, was classified by the factor, and the weights of the various classes ascertained there. As weighed on the islands there is a variation among the skins in respect to their degree of moisture. The scales, moreover, register only to the quarter pound; and the recording of the weights in the midst of the noise in the salt house incident to salting and weighing at the same time, with the subsequent necessary transcription and classification from notebooks, are further factors operating against perfect accuracy in the weights. Deficiencies in the following table are explained by these conditions. As weighed in London, on the other hand, the skins contain some of the salt that was used to cure them. Notwithstanding the impracticability of close comparison, however, it will be interesting to observe how the island weights in general correspond to the London weights taken by a disinterested person.

---

[a] To the season's catch of 11,053 on St. Paul Island, one skin from a subsequent food drive was added to make an even number, as required for shipment.

Island Weights of Skins, 1909 Catch.

NOTE.—On St. Paul Island no skins weighing more than 8½ pounds and only 1 weighing less than 5 pounds were taken during the lessee's killing season. On St. George Island 4 skins weighing more than 8½ pounds were taken during the lessee's killing season, and are held by the government agents on the island pending orders for disposition. With these exceptions, under and over weight skins appearing in the table were taken in drives for the native's food or are hold-overs from the previous season.

NOTE.—The statement furnished from London omits some weights, but, as will be observed, 136 of these are included in the classification.

REJECTIONS FROM DRIVES.

On St. Paul 13,656 animals appeared in the drives during the lessee's sealing season, of which 9,508, or 69 per cent, were killed. There were released from the killing fields 1,110 small and 1,185 large seals, in addition to 1,915 marked or branded seals, composed of 1,315 2-year-olds and 600 3-year-olds. The individual killings varied in the percentages of seals killed from 81 to 39 per cent.

On St. George, during the same season, 4,484 animals appeared in the drives, of which 2,863, or 63 per cent, were killed. There were released 555 large and 306 small seals, in addition to the dismissal of 760 marked seals the ages of which were not segregated.

In 1909, killing on St. Paul was 4 per cent closer, and on St. George 17 per cent closer, than it was in 1908.

[a] For convenience in handling, transfers were made as follows:
Nashua to Craig Brook station 6,233 brook trout eggs.
Neosho to other stations, 35,220 rock bass, 3,000 crappie, and 2,420 bream, all fingerlings.
Northville to other stations, 29,360,000 lake trout eggs.
Detroit to other stations, 60,500,000 whitefish eggs and 32,800,000 pike perch eggs.
Put-in-Bay to other stations, 50,575,000 whitefish eggs and 37,600,000 pike perch eggs.
Quincy to other stations, 7,450 catfish fingerlings, 50 black bass fingerlings, and 350 crappie fingerlings.
Meredosia to Neosho, 150 black bass fingerlings and 750 catfish fingerlings; to Quincy, 14,325 crappie fingerlings. The principal work at the Meredosia station is the collection of fishes from overflowed lands.

QUESTION OF CLOSE KILLING.

After the Alaska Commercial Company had closed its twenty-year lease of the sealing privilege in 1889 there were intimations that to secure its quota in the last year the lessee was forced to drain the herd of every killable bachelor and to resort to unlawful practices to get 100,000 skins. The lease of the North American Commercial Company closed practically in 1909, when its last quota of skins was taken from the islands. To anticipate any questions that may be raised concerning the conduct of sealing during the last year of this as of the former lessee in 1889, it is desirable to discuss the matter here with a view of showing whether, in securing its quota of 1909, the last lessee either violated any law or regulation or did any injury to the herd.

It must be held in mind at the outset that no seals were killed on the islands in 1909 at any time except in the immediate presence of one or more government agents who scrutinized the killing closely and were ready to take active measures to secure enforcement of the law should any violation of it be attempted. Among the laws to be observed are prohibitions against the killing of any female seals or of male seals under 1 year of age. In addition, the regulations prescribe a total quota of 15,000, prohibit the killing of male seals with skins under 5 pounds or over 8½ pounds in weight, and of seals that have been marked and released for breeding purposes. All of these regulations were faithfully enforced by the government agents, who were actually present at each killing, and on the score of compliance with existing law the lessee may be said to be blameless.

There remains, however, the other question, whether, even while observing the law, the lessee killed closer than the safety of the herd would permit; or, in other words, whether the regulations are so loose as to allow such close killing in 1909 as would endanger the future increase of the seals. It may be well to consider this briefly.

It has been stated already that killing on St. Paul Island in 1909 averaged 69 per cent of all seals driven and on St. George Island 63 per cent. This killing was 4 per cent closer on St. Paul and 17 per cent closer on St. George than in 1908, which is to say a killing of about 66 per cent of all seals driven on the two islands. One-third, or 33 per cent, of all animals driven were released. With one animal released out of every three driven it is submitted that killing in 1909 was not close enough to endanger in any way the safety or future increase of the seal herd.

Another point of consideration is the number of animals released from the killing fields in 1909 as contrasted with the number necessary to be released to prevent decrease in the number of breeding

bulls present in 1909. In that year 1,399 breeding bulls were engaged actively with harems. The average life of the breeding bull is five years after he begins full rookery service at eight years. As the herd would thus renew itself in five years, a yearly diminution of one-fifth occurs and is necessary to be provided for. As the herd includes practically 1,400 breeding bulls, it would be necessary to insure that at least one-fifth of this number be provided five years hence, or 280 animals.

During the season of 1909 there occurred 5,831 rejections of seals from the drives. Of these 1,740 were too large to be killed thereafter and 4,091 too small to be killed or included in the breeding reserve. In addition to these there were a number of killables not driven at all, as on August 4 we discovered hauled among the cows on Tolstoi a drive of approximately 600 bachelors, the existence of which theretofore was unknown to the lessee. As the killing season closed on July 31, these animals could not be killed this season.

When we consider that only 280 bulls are required to mature each year to maintain the herd of breeding bulls at its present numbers and that at least 5,000 young males are believed to have survived the season, it can not be believed that the killing in 1909 was too close.

We must now discuss the question whether killing in 1909 was as close as in 1889. In the latter year no record of the number of the seals released from the killing fields was made. It is therefore not possible to ascertain the percentage of seals killed in 1889, nor to compare critically the killing of that year with that of 1909, for which we have exact data.

The main point of difference, however, between the methods practiced in the two years lies in the fact that regulations were in force in 1909 specially designed to prevent too close killing which were not in existence in 1889 and which in fact were not thought of in that year. Before any killing by the lessee was allowed in 1909 2,000 young killable males were reserved for breeding by the agents and marked so that thereafter they would be readily discernible by the clubbers. This reservation of 2,000 represents 13 per cent of the quota allowed the lessee. So that, before the lessee took a single skin in 1909, the herd was safeguarded by a reservation of males equal to 13 per cent of the quota. Under such regulations as these it is impossible at the present time for killing to be too close, even if, after reserving these killables, the lessee "swept the hauling grounds" to secure its quota. It could not sweep them so clean as to eliminate this 13 per cent breeding reserve unless the marked seals themselves were killed, and there is plenty of evidence to show that these marked seals were carefully guarded when they appeared in the drives.

Such killing as was done in 1909 was conducted strictly in accordance with law and regulations. The Government prescribed a quota of 15,000 for the lessee and virtually said: "After we have secured our breeding reserve, you are allowed to kill every seal on the hauling grounds that may be taken under existing law and regulations until you get your quota. We will see that you do not kill our breeding reserve; the law prohibits your killing females or seals under 1 year of age, and if you take skins weighing less than 5 or more than 8½ pounds we will not allow you to ship them, but will deduct them from the quota you would otherwise be allowed to ship." This was the exact situation in 1909, and in the killing no law or regulation was disregarded. During the lessee's killing season only 1 skin on St. Paul Island and 4 on St. George Island were taken contrary to regulations out of a total of over 12,000, and these seals were killed not designedly, but through accident.

From the foregoing it can be summed up: First, that every law and regulation safeguarding killing in 1909 was faithfully enforced; second, that one seal out of every three driven by the lessee in that year was released; and, third, that before any killing by the lessee was allowed a breeding reservation equal to 13 per cent of the quota was created and carefully guarded from slaughter. This, in my opinion, is sufficient evidence to convince even the skeptical that any charge of irregularity concerning the killing in 1909 can not be substantiated.

It is foolish to curtail the killing of bachelors on land while the islands are surrounded by a large fleet of pelagic schooners, hardly 3 miles offshore, ready to kill every seal that leaves the rookeries to go to sea. After providing an ample breeding reserve, it is good policy to kill every seal that may be killed with due regard to the safety of the herd. Restriction of killing on land should be discussed only after sea killing is stopped.

Personally I am in favor of killing on land even closer than 66 per cent, and of continuing such close killing until either the seals are reduced to a small number or the question of pelagic sealing is settled favorably.

MAINTENANCE OF QUOTA.

ANNUAL CATCHES SINCE 1903.

Since 1904 the annual quota of skins has been maintained at approximately 15,000. From this the natural assumption would be that the breeding herd of females has not diminished during this period, as otherwise the stock of bachelors would have decreased coincidently.

It is generally accepted that the sexes of seals are born in equal numbers. If the herd of bachelors has remained stable without

diminution during these years, we must accept the conclusion that the number of breeding females which produce these bachelors also have remained at a state of equilibrium, notwithstanding the heavy killing of females in the open sea by pelagic sealers.

Since 1903 the annual catches of bachelors on the islands have been as follows, the figures given representing the annual shipments of skins from the islands by the lessee:

1903	19,292
1904	13,128
1905	14,368
1906	14,476
1907	14,964
1908	14,996
1909	14,331

From an examination of these figures it appears that the lessee took over 19,000 skins in 1903; that its catch dropped to 13,000 in 1904, and that annually thereafter it killed practically 15,000 seals until 1909.

If these figures were susceptible of no other explanation than that the number of bachelors had not diminished, this conclusion would have to be accepted without argument. If, however, other facts have relevancy in a consideration of the cause of this stability of the catch, they should be examined before the conclusion is accepted that no decrease in the breeding herd has occurred during this period.

ANALYSIS OF CONDITIONS.

Previous to 1904 no restriction upon the size of bachelors to be killed was enforced. The annual quotas allowed were so ample as to carry permission to kill every available bachelor appearing in the drives. In its operations the lessee killed every 4-year-old, every 3-year-old, and every 2-year-old driven up that had not a defective skin. Its rejections of seals from the killing fields were confined to those seals only with bad skins, to those young wigs too large for the market, or to such few yearlings as appeared in the last drives of the season. All other male seals were killed. In 1903 the rejections of small seals numbered only 1,185 on St. Paul, and at least one-fourth of these were dismissed from the two food drives made by the government agents during the period between August 1 and 10. With so small a proportion of rejections in 1903 and the large catch of that year, we must conclude that the lessee killed almost every available seal that appeared. Furthermore, it anticipated its next year's catch by killing all of the 2-year-olds that hauled up and that could be driven. Such as escaped were killable the following year as 3-year-olds. The lessee, in plain

terms, was "living from hand to mouth," killing all it could get and saving none; depending for its next year's catch solely upon the increment of 2-year-olds and such larger seals as had accidentally escaped clubbing the year previous. Such practice could be termed too close killing.

In 1904, on the other hand, occurred for the first time the enforcement of the regulations designed to prevent too close killing, by the exemption of 4-year-olds from slaughter, the establishment of a minimum weight of 5½ pounds on sealskins to be taken, and a reservation of 2,000 young males for breeding purposes. These regulations of 1904 changed completely the conditions surrounding the killing of seals on the islands. It reduced the catch in one year from 19,000 to 13,000, created through dismissals a reserve of 7,500 young males to maintain the quota for succeeding years, and provided means for insuring recruits to the rapidly decreasing stock of breeding bulls. The change amounted to a transition from the condition of practical nonregulation of killing to one of careful regulation.

Since the quota was reduced in one year (1903–4) from 19,000 to 13,000, not by natural conditions, but by the enforcement of arbitrary restrictions upon the catch, it might well follow that the catches of other years as well were influenced by other agencies than the natural state of the herd. For this purpose a brief résumé of the conditions attending the several years' killings will be made:

1903.—The lessee shipped over 19,000 skins and on St. Paul Island only 1,185 small seals were released from the killing field.[a]

1904.—After the enforcement of the regulations requiring the exemption of 4-year-olds from killing, the establishment of a 5½-pound minimum weight, and the reservation of young males for breeders, the number of skins shipped as quota was reduced to 13,128. On the other hand, the rejection of small seals amounted to 10,181. These 10,181 rejections created a reserve of surplus bachelors which, as 3-year-olds, would aid the catch of 1905, and emphatically relieved the situation as regards close killing.

In view of this large number of rejections it is not proper to say that the lessee could not have secured its quota in this year. The reason why 15,000 were not taken instead of only 13,000 is due to the fact that such great caution was enjoined upon the lessee in securing the enforcement of the new regulations that seals which were properly killable were allowed to escape.

1905.—In this year 14,368 skins were shipped. The St. Paul quota of 13,000 was secured, with 59 per cent killed of the whole number driven, while the St. George Island quota, 2,000, was not obtained. As the percentage of killed on this latter island was, however, only

[a] Records of rejections on St. George for 1903 are incomplete.

26, it must be concluded that enough eligible seals escaped from the killing fields to have filled the quota.

In 1905 the reserve of bachelors was further maintained by over 10,000 rejections of small seals made during the lessee's sealing season. As the quota of 1905 was aided by the large number of rejections in the preceding year, so the 1906 quota must be considered as aided by a similar number of rejections in 1905.

1906.—For this year a quota of 14,476 was shipped, of which 12,536 were secured from St. Paul Island toward its quota of 13,000, while 1,940 were shipped from St. George Island toward its quota of 2,000. The percentage killed on St. Paul was 59, while on St. George it was 51, an increase on the latter island over the preceding year of 25 per cent. In this year occurred, in addition, an important change in the regulations, namely, that the minimum weight of skins to be taken was reduced from 5½ to 5 pounds. This had the effect of allowing the killing of several thousand young seals which heretofore would have been released and included in the reserve of young males from which a portion of the next year's catch would be obtained. With this material aid, however, the quota on St. Paul was not secured.

We find here a decided decrease in the bachelor herd. To secure the quota on St. George Island killing had to be 25 per cent closer than the year previous, even when aided by the reduction in the limit of weight and the savings of bachelors from previous years. In spite of the reduction in weight the quota could not be obtained on St. Paul Island. Had the number of bachelors in existence remained the same in 1906 as in 1905 the reduction of the minimum weight and the consequent inclusion among the killables of several thousands of young males of a size hitherto exempt would have made it possible to secure the quota before the expiration of the sealing season. But it is a fact that it was not possible to secure the St. Paul quota even by sealing until the last day and with the minimum weight lowered to 5 pounds. This certainly shows that fewer bachelors were on St. Paul in 1906 than formerly.

The rejections from the sealing fields in 1906, of course, were affected by this lowering of the weight, and were 7,217, as against over 10,000 in 1905, a loss of over 3,000. This, however, was still large enough to save a number of bachelors for the next year's quota.

1907.—Practically the entire quota of 15,000 was obtained and was secured before the end of this season—the condition which should have occurred in 1906 had not a scarcity of bachelors been encountered then. St. Paul's quota of 12,400 was obtained by July 28, while St. George's 2,600 was obtained by July 24. The lessee killed more closely, however, as shown by the percentages of killed—68 for St. Paul and 44 for St. George. The rejections from the killing

fields, also, were less numerous by 2,500 than in 1906. This shows at least that the seals had not increased. It is not out of the way, however, to infer that no decrease in the bachelor herd had occurred since 1906.

1908.—The entire quota of 15,000, practically, was obtained this year, but only after sealing on St. Paul until the end of the season. The St. George quota, however, was obtained by July 25. The percentage of killing on St. Paul was 5 less than the year before, while that of St. George was 2 greater. The number of small rejections in this year was 6,092, or in round numbers 1,300 more than the preceding year. There is everything in the killing statistics of this year to show that the bachelor herd did not diminish in the interval between 1907 and 1908.

1909.—A decided decrease is apparent in the record of this season. Not only was the quota not secured, but the rejections from the killing field were less than at any time since 1903.

The number of skins secured and shipped was 14,368, of which 37 were charged to the preceding year. The percentage of killed was 69 on St. Paul, an increase of 4 per cent, while on St. George it was 63, or 17 per cent more than 1908. The number of small rejections was only 1,416 in addition to 2,675 rejections of marked bachelors, or 4,091 in all, as against 6,092 the year before.

As, outside of the breeding reserve, only 1,416 rejections of small seals were made in 1909, we may safely consider the bachelor reserve to have been almost eliminated.

SUMMARY AND INTERPRETATION OF CONDITIONS.

After this more or less detailed analysis of the killings during the years since 1903 we may summarize the main points as follows:

1. The quotas for 1904 and 1905 were not obtained because of stringent enforcement of regulations designed to prevent close killing.

2. These regulations were partially relieved of their severity in 1906, when the minimum weight was reduced to 5 pounds. Nevertheless, in this year the quota was not secured because of scarcity of seals.

3. In 1907 and 1908 the quotas were secured without special difficulty, although the rejections from drives were lessened from the number in 1906.

4. In 1909 not only was the quota not secured, but the rejections were less than at any time since 1903, and the percentage of killing was higher.

We may reasonably infer that in 1904 a quota of 15,000 was less than the herd would have afforded had the same methods of close killing been continued as were followed in 1903 and previously. From the statistics we might gather that the catch of 1904 under

the same conditions would have been nearly what it was in 1903. Yet we can not say that 19,000 seals, or anything near that number, could have been secured in 1909. In other words, the herd has gradually decreased since 1903 from a point where it allowed a catch of over 19,000 to a point, in 1909, where it could not afford 16,500, if we count the bachelors marked for breeding as a portion of the yield of the herd. We have marked decreases in 1906 and again in 1909, with a probable equilibrium between those years. But the trend of the bachelor herd has been toward gradual decrease, and this can be better understood when an observation is extended over a period of years.

The question presents itself: How, if a gradual decrease occurred, was the quota maintained at approximately the same number? The answer is that the quota of 15,000, when first fixed, was smaller than the yield of the herd; that the quotas of the years following were aided in large part from the rejections from previous years, and that not until 1909 did the herd diminish to a point where it could not yield 15,000 skins annually. It was really not until 1909 that the rejections became practically nil, and even with that the quota could not be filled.

It is with considerable hesitancy that I advance this conclusion that the decrease in the herd of breeding seals has been less rapid than would otherwise appear. During the period following 1903 whole rookery areas gradually have been denuded of breeding seals, the rookeries themselves have shrunk, and massed areas of breeding seals have become smaller. Every other indication would point to the supposed fact that the breeding herd had diminished more rapidly than the catches of bachelors would indicate. As it stands, however, a material decrease in the herd is apparent in the inability of the lessee this last season to secure a quota of skins which could have been taken without undue effort in 1903.

EFFECT OF SAVING 2-YEAR-OLDS.

When, in 1904, the catch of skins was reduced by regulation from 19,000 to 13,000, a large number of small bachelors was released. As stated heretofore, this catch of 13,000 did not represent by any means all the skins the lessee could have taken had the same methods of close killing as practiced in preceding years been permitted. Had the lessee been allowed in 1904 to sweep the hauling grounds of every bachelor appearing there, as in 1903, the catch for 1904 would nearly have equaled that of the preceding year.

As this decrease in the catch in 1904 had its cause solely in the enforcement of certain arbitrarily restrictive measures, it had no connection with the number of breeding females in the herd. Its effect was to create a reserve of young animals numbering probably 7,500.

The result of the creation of this reserve was to place the herd in a condition which represented more nearly what might be termed its normal status, and, secondly, it insured a certain stability of the next year's catch of skins independently of that year's increment of young killables.

The normal status of the bachelor herd is reached when the greater portion of the take of skins consists of 3-year-olds. The reason for this lies in the fact that a 3-year-old has a prime skin that brings the highest price in the market. As the 3-year-old skin is more valuable than that of a 2-year-old, it follows that proper management should maintain such conditions as would result in the catch being secured mainly from the prime or 3-year-old skins, rather than from the less valuable 2-year-olds. This can be done only by the maintenance of a reserve of 2-year-olds which, being protected from slaughter at that age, would furnish the proper number of 3-year-old skins the following season.

The immunizing from killing of this large number of 2-year-olds in 1904 resulted in bringing nearly that number of prime 3-year-olds back to the islands in 1905. The effect was to permit the catch of 1905 to be composed of 50 per cent of prime 3-year-old skins, whereas previously only a thousand or so of 3-year-olds were included. That the value of the company's catch was enhanced by these methods of selection is shown by the fact that the average selling price of their skins in 1904 and 1905 was $37, while in 1903 it was only about $29.50.

When the lessee, as in 1903, swept the hauling grounds of every bachelor appearing there, necessarily many small seals were killed whose skins would bring much less than those of the prime 3-year-olds. This, of course, was waste. Although deprived of some of these small seals in 1904 by the operation of the regulations, the lessee received back in 1905 such a number of prime 3-year-olds that the loss of one year was more than equaled by the gain of the next, with the added advantage of having to kill fewer animals to secure the same profit.

When such a reserve of young bachelors is created, thereby insuring in a degree the permanency of the next year's catch, this reservation would have the effect of obscuring, to a degree at least, any decrease in the breeding herd that would cause fewer young males to appear upon the killing field.

When, for example, as in 1903, the lessee depended for its catch mainly upon the influx of 2-year-olds that theretofore had been too small to kill, its catch had close relation to the number of breeding cows that, two seasons previously, had brought forth the 2-year-olds it expected to kill. It could look nowhere else for its catch. If the births two years previously were more numerous the catch would be larger; if less numerous the catch would be smaller. Under these

conditions the catch of any year would be quickly responsive to a lessening or enlarging of the number of births two years previously.

With the creation, however, of a reserve of bachelors, the lessee would be able to expect a portion of its catch from this reserve instead of from the increment from the breeding herd alone. As it would be justified in counting upon a considerable number of 3-year-old skins from the reserve, a correspondingly smaller number of 2-year-olds from the increment of young seals would be needed to complete its quota.

This indicates that the maintenance of a bachelor reserve would obscure to a degree the effect on bachelors of a reduction of the breeding herd. Without this reserve the shrinkage would be quickly felt; with it, however, the loss in new seals would be met by the bachelor reserve and the catch maintained. This is one of the reasons why the land catches on the Pribilof Islands have been maintained at a relatively stable figure since 1904, and the reduction in the number of young seals, resulting from a depletion of the breeding cows, not immediately indicated by a simultaneous reduction of the bachelor catch.

REDUCTION OF BACHELOR RESERVE.

It must not be overlooked that the bachelor reserve represented by the number of small rejections from the killing field has been almost eliminated. Beginning in 1904 with over 10,000 rejections of these males, the reserve has fallen steadily to 4,000 rejections in 1909, including those among the marked bachelors. Its steady diminution during this period apparently indicates that to maintain the quota at a stable figure this reserve had to be drawn upon more heavily every succeeding year; or conversely, the rejections each year became fewer in order to secure the quota. It certainly is true that a steady but gradual reduction occurred in the number of bachelors rejected, and had such reduction not been made the quota would have suffered.

The reduction of this reserve will make it a matter of difficulty to secure a quota in 1910 approaching in size that of 1909. With fewer of the older animals to draw upon, dependence will be had mainly upon the young or 2-year-olds. With the chance that there will be fewer of these than in 1909, it would appear problematical whether enough can be found to equal or approach the catch of 1909.

RATIO OF BACHELORS TO WHOLE HERD.

In 1897 the investigation made by the commission of which Dr. David Starr Jordan was chief disclosed a ratio of bachelors to the whole herd of 1 to 20. That ratio was used by him in his criticisms of the accuracy of H. W. Elliott's censuses based on acreage measure-

ments in 1874 and 1890. Subsequently, as stated in Mr. E. W. Sims's report[a] on the seal islands, in 1906, the relation of bachelors to the whole herd in 1904 and 1905, according to the censuses made by the agent in charge of seal fisheries for those years, was found to be, respectively, 1 to 16 and 1 to 14.

In 1909, by such methods of computation as are available, the whole herd of seals numbers approximately 133,000, while the catch of bachelors was 14,331. Added to the latter, to form an idea of the total bachelor yield of the herd, should be 2,000 bachelors marked and released, making a total possible catch of bachelors for 1909 of 16,331. When we contrast this yield of bachelors for 1909 with the number of the whole herd in that year, we have a relation of bachelors to the whole herd of 1 to 9. The following table will show the various ratios for the years mentioned:

RATIO OF BACHELORS IN CERTAIN YEARS.

Year.	Bachelors killed.	Whole herd.	Bachelors released.	Ratio of catch to whole herd.
1897	20,766	402,850		1 to 20.
1904	13,128	243,103	2,054	1 to 16.
1905	14,368	223,009	2,174	1 to 14.
1909	14,331	133,000	2,000	1 to 9.

This would show that the ratio which the catch of bachelors bears to the whole herd has changed from 1 to 20 in 1897 to 1 to 9 in 1909.

The percentage of bachelors dismissed from the killing field in 1897 was 41 per cent; in 1904, 44 per cent; in 1905, 40 per cent; and in 1909, 32 per cent. This shows that killing in 1909 was 9 per cent closer than in 1897, and would account partially for the difference in the ratio, but not altogether, in my mind. Had killing in 1909 been no closer than in 1897 (59 per cent), the whole number killed would have been 10,603, which, added to the number marked and released, would have made a ratio of 1 to 11 in 1909.

This demonstrates that there was in 1909 a larger proportion of bachelors present to the whole herd than was shown to be present in 1897. In fact, the proportion seems to have increased gradually since 1897. Why this is so is difficult to explain. With a gradually diminishing herd, the number of bachelors proportionately has increased so that the annual catches of skins do not show the same rate of diminution as the herd in general.

It may be possible that the death rate among young pups has been lessened. It has been estimated heretofore that 50 per cent of pups die in their first migration, or rather that only 50 per cent reappear as yearlings the year after their birth. This was supposed to be due to

[a] Report on the Alaskan Fur-Seal Fisheries, by Edwin W. Sims, Department of Commerce and Labor, August 31, 1906.

their inability as pups to provide food for themselves and to escape from their natural enemies. It was due also to a heavy death rate among these pups on shore from disease. It is altogether probable that the death rate from disease on shore that affected pups in 1897 has since been reduced greatly through the abandonment by seals of areas that were supposed to be infected. This would allow a greater number of pups to return as yearlings than heretofore and would increase the number of bachelors in proportion to the whole herd. It would also insure the return of a greater number of yearling females, and would assist in maintaining the breeding herd despite pelagic killing of cows. It is possible also that the allowance of a 50 per cent mortality in pups was too high even in 1897, but I am inclined to believe rather that the death rate has changed since then and that more pups survive now than formerly.

The proportion which the pelagic catch bears to the whole herd has changed also. In 1897 the pelagic catch, 24,321, bore the same relation to the whole herd, 402,850, as 1 to 16. In 1908 it was as 1 to 8 (18,151 : 146,636). From this it would seem that the pelagic sealers are killing twice as many seals in proportion as they did eleven years ago. This is another singular fact in connection with the subject, showing that conditions at the present time differ entirely from previous years.

It may be that by the methods of estimation used, the number in the whole herd in recent years has been placed too low, or rather, that there are more seals in the herd than are given in the estimates or censuses. It is either in this possibility or the one already mentioned—that the mortality among pups is less than hitherto—that the cause of this change of relation of bachelor catch to the whole herd must be sought.

NUMERICAL STATUS OF THE SEAL HERD.

COUNTS OF HAREMS AND BULLS.

The usual counts of harems were made on the two islands during the period of July 13–16. These counts were made by the agents and a special representative of the Bureau of Fisheries, Mr. G. A. Clark, and were made carefully. The count for St. Paul Island follows:

COUNT OF HAREMS ON ST. PAUL ISLAND, 1909.

Date.	Rookery.	Harems.	Idle bulls.	Quitters.	Water bulls.	Bulls on hauling grounds.
1909.						
July 12	Lagoon	12	3	1	.....	.....
12	Northeast Point	229	33	a 42	.....	.....
12	Little Polavina	19	2	1	.....	.....
12	Polavina Cliffs	23	.....	1	.....	.....
12	Polavina	42	3	15	.....	.....
15	Gorbatch Cliffs	2	1	.....	.....	.....
15	Gorbatch	118	20	6	.....	20
15	Ardiguen	11	2	.....	.....	.....
15	Reef	184	13	22	.....	32
15	Tolstoi Cliffs	25	4	1	.....	.....
15	Tolstoi	87	14	5	.....	7
15	Ketovi	51	9	3	6	.....
15	Amphitheater	7	3	.....	.....	.....
15	Lukanin	41	3	1	4	.....
16	Zapadni Reef	11	1	1	.....	.....
16	Little Zapadni	62	9	4	.....	9
16	Zapadni	147	20	13	3	15
16	Sea Lion Rock	61	.....	.....	.....	.....
	Total	1,132	140	116	13	83

a Includes water bulls.

Contrasting the total number of harems and bulls found on St. Paul Island in 1909 with the number found in 1908, exclusive of Sea Lion Rock, the following changes are to be noted:

COMPARISON OF HAREMS, ST. PAUL ISLAND, 1908 AND 1909.

Year.	Harems.	Idle.	Quitters.	Water bulls.	Hauling-ground bulls.
1909	1,071	140	116	13	83
1908	1,062	90	45	68	.....
Difference	+9	+50	+71	−55	.....

On St. Paul Island, therefore, while there occurred an increase of only 9 harems between 1908 and 1909, the total number of adult bulls present on the rookeries (harem masters, idle, and quitters) was increased by 130 individuals.

On St. George Island, in 1909, harems were counted on July 14–16 by the agents, and later these counts were verified by one of the agents and Mr. G. A. Clark. A detailed list of the bulls found on St. George Island, as disclosed by the counts mentioned, follows:

COUNT OF HAREMS ON ST. GEORGE ISLAND, 1909.

Date.	Rookery.	Harems.	Idle bulls.	Quitters.	Hauling-ground bulls.
1909.					
July 14	Little East	5			
14	East Reef	25		6	
14	East Cliffs	42		5	
14	Staraya Artel	42	10	7	
16	Zapadni	44	9		15
15	North	109	13	5	
	Total	267	32	23	15

A comparison between the totals of 1908 and 1909 shows the following changes as having occurred on St. George:

COMPARISON OF HAREMS, ST. GEORGE ISLAND, 1908 AND 1909.

Year.	Harems.	Idle.	Quitters.	Hauling-ground bulls.
1909	267	32	23	15
1908	241	34	27	(a)
Difference	+ 26	− 2	− 4	

a No data.

It may be noted from the above table that an increase of 26 harems occurred on St. George Island, or 10 per cent. The idle bulls and quitters show a slight decrease.

For the two islands, therefore, the counts made in 1909 show a net increase of 35 harems, 48 idle bulls, and 67 quitters, or a total of 150 full-grown bulls.

It may be noted that the water bulls on St. Paul Island decreased 55 between 1908 and 1909. These are the immature 5 and 6 year olds hanging about the water fronts of rookeries. They are not breeding bulls because they are not stationed in positions where they may serve cows, although in the fall they will haul up on the rookeries and annoy the cows after the adult breeding bulls have relaxed their vigilant harem control.

The decrease in this class of animals may have been caused by the possible fact that, at the particular time these counts were made, weather conditions or some other cause may have operated to bring fewer of these animals on shore than normally.

It is more probable, however, that this decrease has its cause further back than the present summer and is due to more tangible

reasons. It can be sought in the large number of young seals released from the killing fields in 1904 and following years.

In that year (1904), according to the statistics of rejections, 8,019 small seals were released uninjured from the drives brought to the killing fields, in addition to 2,162 young seals marked and released for breeding purposes. This made a grand total of 10,181 young seals released in this one year (1904). In 1905, 10,288 rejections of the same character were made.

Take, for example, the 2-year-olds of 1904, of which there were approximately 8,000 rejections. These seals would be 3-year-olds in 1905, 4-year-olds in 1906, 5-year-olds in 1907, and 6-year-olds in 1908. The 2-year-olds of 1905 would be 5-year-olds in 1908, one year behind those of 1904.

Theoretically, therefore, in 1907 and 1908 we would have a large number of young males which would be either 5 or 6 year olds. At this age they would be true water bulls—not old enough to fight their way upon the rookeries to serve cows, but old enough to be obsessed by the breeding instinct and to loiter about the water fronts of rookeries flirting with cows coming and going to feed. For this reason, in 1907 and 1908 we should have had more of this class of young males than hitherto.

A reference to the annual reports of 1907 and 1908 will show that this increase occurred. In 1907, 100 water bulls were noted on the rookery fronts of St. Paul Island, where, before, the number was so small as to fail to suggest the advisability of enumeration. In 1908 only 68 water bulls were noted, and from this it is to be inferred that some of the water bulls of 1907 graduated into the idle bull or 7-year-old class of 1908. This is further borne out by the increase of 29 idle bulls in 1908. In 1909 these young bulls should have progressed into active harem masters and increased the number of harems. This is also borne out by the fact that in 1909 on St. Paul Island an increase of 9 occurred in the number of harems, the first increase in the number of harems that has occurred on St. Paul for years.

But why should the supply of 5 and 6 year old males be less in 1908 than in 1909? Because the practice of releasing 10,000 annually from the killing fields was continued only through the years 1904 and 1905. In 1906 only about 7,000 were released, and in 1907 only about 4,000. This lessening of the number of rejections in previous years must find its echo in the lessening number of young bulls apparent several years thereafter.

PURPOSE OF BREEDING RESERVATION.

Since 1904 an annual reservation has been made of 1,000 3-year-old males, together with 1,000 2-year-old males designed to insure a supply of 3-year-olds the season following. The purpose of this

reservation is to supply young males in sufficient numbers to meet the heavy death rate which has been demonstrated by experience to occur among adult rookery bulls. The heavy mortality among this class of fur seals has been apparent in the steady decrease in the number of bulls present on rookeries during observations extending over ten years. To check this decrease, by providing a sufficient increment of young bulls, was the object of the plan of reserving young male seals by marking them in such manner as to prevent their being killed by clubbers on the sealing fields.

During the six years from 1904 to 1909, both inclusive, 12,000 young males have been so reserved. Of these, 6,000 were 2-year-olds and 6,000 3-year olds at the time of reservation. As those seals reserved in 1904 and 1905 now would be coming upon the rookeries as breeders, it is both interesting and desirable that we should form an idea of the number of these young bulls we should expect to appear upon the rookeries.

Any attempt to compute the number of reserved 2-year-olds which might survive as breeders would be futile, the mark put upon them not being permanent and protecting them only for the first year. These 2-year-olds were reserved solely for the purpose of insuring a supply of 3-year-olds the next year and to prevent too close killing. It was understood at the time the plan was inaugurated that the 2-year-olds would be liable to be killed the following year. Their exemption from slaughter as 2-year-olds, however, would insure their presence the next year as 3-year-olds, and these latter were depended upon to form the actual breeding reserve. For this reason, therefore, in attempting to compute the probable increase, only the reservation of 3-year-olds should be considered and not that of the 2-year-olds, the reservation of which acts merely as a "feeder" to that of the 3-year-olds.

The 3-year-olds, on the other hand, become 4-year-olds the next year, the killing of which is prohibited by regulation. Thereafter they are too large to be killed by the clubbers. Few of them, in fact, appear later upon the field, but instead frequent the rookery fronts worrying the cows. This class of young males, therefore, we may safely attempt to follow through succeeding years and to estimate what number might be expected to appear from year to year thereafter.

INCREASE OF BULLS THROUGH RESERVATIONS.

During the six years mentioned 6,000 3-year-olds were reserved for breeding, 1,000 each year. To follow their progress through the years following, allowance should be made for a 10 per cent mortality from natural causes. What mortality they suffer from pelagic sealing, although severe, need not be dealt with here, as our object merely

is to decide how many of these bachelors under normal conditions might be expected to mature as bulls.

A table constructed on this basis follows:

INCREMENT OF BULLS FROM BREEDING RESERVATIONS.

Age.	1904.	1905.	1906.	1907.	1908.	1909.
3-year-olds	1,000	1,000	1,000	1,000	1,000	1,000
4-year-olds		900	900	900	900	900
5-year-olds			810	810	810	810
6-year-olds				729	729	729
7-year-olds					647	647
Adult bulls						583

From this table we can see that, theoretically, we should have in 1909, from the reservations of 3-year-olds made in 1904 and 1905, an increment of 583 adult, or 8-year-old bulls, and 647 7-year-olds, or quitters. This does not mean, of course, that the number of bulls present in 1908 would be increased by the number of new bulls noted above. A number of the 1908 bulls would have died by the following year. It means that this number of young bulls would be available to offset the mortality among adult bulls occurring during the interval between the seasons of 1908 and 1909. Any increase in bulls noted in the latter year would represent the excess of incoming young bulls over the loss by death of old bulls.

It will now be interesting to note to what degree this theoretical computation agrees with the facts as demonstrated by the actual counts made during the last season. The table shows that 583 new full-grown bulls should be present in 1909. The count of harems made in 1909 shows that the number of harems in 1908 has been maintained and that we have in 1909 an increase of 35 harems on the two islands, and of 48 full-grown adult bulls that were without cows, a net increase in adult bulls of 83, in addition to an increase of 67 in the 7-year-old quitter class.

This actual increase in the number of bulls shows that the theoretical computation is correct in so far as to indicate a comfortable increase in bulls in 1909. The number of these new bulls that did actually take station on the rookeries is undeterminable, and to that extent we can not verify the table. We do know that a number of young bulls had harems in 1909 for the first time, and that these incoming young bulls were sufficient not only to fill the gaps created by the death of old bulls but to increase the actual number apparent on the rookeries by 83 harem masters and idle. When we consider further the increase of 67 quitters, or 7-year-olds, a total increase of 150 breeding males, we may feel that we have received, in a modified degree at least, the benefit of the reservations which the theoretical computation indicates should have been felt.

Of course, not a few individuals of the reservations of 1904 and 1905 were killed by pelagic sealers. Those of 1904 now living had to elude the efforts to capture them in the sea made during a period of six years. The cumulative effect of six years' sea hunting upon a given class of animals, such as these young males released in 1904, must be severe enough to deplete the original number materially. No one will claim that of the original 1,000 3-year-olds released in 1904 all came through to adult estate with a loss attributable only to natural mortality. Quite a large percentage died from pelagic sealing, but enough escaped the vicissitudes of seal life not only to fill all the places made vacant by the deaths of old bulls, but to reenforce that class to the point of actual expansion.

Notwithstanding the assured success of this experiment of reserving young males, it may be claimed that the result should have been more pronounced, or, in other words, that more bulls should have appeared than actually did. Theoretically more should have appeared, but our theories are based upon the knowledge of only a few facts connected with seal life after the seals leave the land. What the actual mortality is among these animals from their natural enemies and pelagic sealing can not be ascertained, but undoubtedly it is large. From the experiment we have learned simply that a reservation of 2,000 bachelors will not deliver the entire number on the rookeries as bulls five years hence, and that, if we want more bulls than actually appeared, we must have a larger reservation.

SIZE OF RESERVATION TO EFFECT INCREASE IN BULLS.

In 1904 there were approximately 2,300 adult bulls on the rookeries, and in that year the first reservation of 1,000 3-year-olds was made. No account is taken of the 1,000 2-year-olds made at the same time, for the reason already given that these latter are always liable to be killed the succeeding year on land and were reserved for the purpose merely of insuring a supply of 3-year-olds for the next year's reservation.

These 1,000 3-year-olds represented nearly 50 per cent of the number of active breeding bulls present in 1904. When the years necessary for their full growth had passed it is found that the increment of the survivors of this 50 per cent reservation was sufficient only to form a slight excess over the number of bulls present the preceding year. In other words, it is found that a reservation equal to 50 per cent of the adult bulls present was hardly more than enough to meet the drains from the usual mortality among rookery bulls.

From these facts, hardly sufficient though they be, we might deduce the tentative principle to be observed in future, should further effort be made by reservation of 3-year-olds to meet and check

a steady decrease in rookery bulls, namely, that such reservation must equal at least 50 per cent of the adult bulls in existence at the time the reservation is first made.

CHANGE IN HAREMS BY ROOKERIES.

We have seen from the foregoing that an increase of 9 harems occurred on St. Paul Island and of 26 on St. George Island. This increase represents a percentage of only eight-tenths of 1 per cent on St. Paul and of over 10 per cent on St. George. The counts disclose an increase upon all the rookeries on St. George excepting one, and that one, Little East, is the same as in 1908, while on St. Paul only 1 of the 4 large rookeries (Gorbatch) shows any increase whatever. With this single exception, such increase on St. Paul as did occur took place on the smaller rookeries.

A count of the bulls on all rookeries in 1908 and 1909, with a statement of the changes occurring during the interval, follows:

COUNT OF BULLS ON ALL ROOKERIES, 1908 AND 1909.

Rookery.	Harem.		Increase (+) or decrease (−).
	1908.	1909.	
St. Paul:			
Ardiguen	8	11	+ 3
Reef	200	184	−16
Ketovi	42	51	+ 9
Amphitheater	6	7	+ 1
Lukanin	44	41	− 3
Tolstoi	88	87	− 1
Tolstoi Cliffs	20	25	+ 5
Lagoon	13	12	− 1
Northeast Point	237	229	− 8
Little Polavina	16	19	+ 3
Polavina Cliffs	24	23	− 1
Polavina	36	42	+ 6
Zapadni	148	147	− 1
Little Zapadni	64	62	− 2
Zapadni Reef	10	11	+ 1
Gorbatch Cliffs	3	2	− 1
Gorbatch	103	118	+15
St. George:			
Little East	5	5	.....
East Reef	20	25	+ 5
East Cliffs	41	42	+ 1
Staraya Artel	41	42	+ 1
Zapadni	40	44	+ 4
North	94	109	+15

This fact, that the rookeries on St. George Island show increase in bulls in a marked degree, is strongly corroborative of the tentative conclusion advanced by me in 1908, that the continued disturbance of seals in the water about St. Paul Island by the pelagic sealers has had the effect of driving off seals to the other island, where they suffer but little annoyance from the sealers. In 1908 the change in the habits of the bachelors in hauling on the Reef, where they were least disturbed, in preference to Northeast Point, where two-thirds of the

fleet gathered, was plainly noticeable. This year the fleet gathered mainly off Southwest Point, and as a result no large drives were made from the Reef, as was the case in the two years preceding, while as many bachelors were found at Northeast Point as at any other rookery. This situation in 1909 is more a return to normal than a change, but indicates that seals can be influenced in hauling by conditions extraneous to their normal environment.

The cause of the fact that the increase in bulls on St. Paul occurred only on smaller rookeries excepting one, might lie in the fact that on the smaller rookeries the young bulls had a better opportunity of lodgment close to the cows than on the larger ones, where the average harem was smaller.

COUNTS OF PUPS AND AVERAGE HAREM.

Counts of pups were made last summer on several rookeries with the object of determining whether or not the breeding females have diminished, as well as the size of the average harem, by means of which estimates of the whole number of breeding cows on the two islands might be made.

St. Paul Island.—Counts of pups were made upon certain rookeries on St. Paul in 1909 and are detailed in the following table:

COUNTS OF PUPS ON ROOKERIES OF ST. PAUL ISLAND, 1909.

Date.	Rookery.	Live pups.	Dead pups.	Total.
1909.				
Aug. 2	Ketovi	1,669	60	1,729
2	Amphitheater	246	4	250
4	Lagoon	693	22	715
4	Tolstoi Cliffs	1,397	55	1,452
4	Zapadni Reef	309	10	319
	Total	4,314	151	4,465

It was originally my purpose to count the pups on only Ketovi and Amphitheater, omitting all other rookeries, to avoid driving into the water any greater number of breeding cows than necessary. Counts of other rookeries were made, however, at the request of Mr. G. A. Clark, special representative of the Bureau of Fisheries, for comparison of their present condition with their status in 1897, when the pups thereon were counted by the fur-seal commission.

The rookeries on which pups were counted on St. Paul in 1909 contained 106 harems at the height of the breeding season. As 4,465 live and dead pups were found on the same area, and as each pup represents a breeding cow, each harem on this space would have on an average 42.1 cows.

This represents, as has been stated, an average harem based on the entire count of pups made. The average harems on the individual rookeries vary greatly. The average harem on Zapadni Reef is 29, while that on Lagoon is 59.5. Tolstoi Cliffs, on which 1,452 pups were found, had an average harem of 58. For convenience, the average harem on each rookery on which pups were counted is given below:

AVERAGE HAREMS ON ROOKERIES ON ST. PAUL ISLAND.

Rookery.	Live and dead pups.	Harems.	Average harem.
Ketovi and Amphitheater	1,979	58	34.1
Lagoon	715	12	59.5
Tolstoi Cliffs	1,452	25	58.0
Zapadni Reef	319	11	29.0
Total	4,465	106	42.1

On St. Paul in 1908 the pups on Ketovi and Amphitheater only were counted. For this reason, comparison between the counts in 1908 and 1909 can be made only for these rookeries. Such comparison shows:

COMPARISON OF COUNTS OF PUPS, ST. PAUL, 1908 AND 1909.

Year.	Rookery.	Live pups.	Dead pups.	Total.
1908	Ketovi and Amphitheater	1,877	83	1,960
1909	do	1,915	64	1,979
	Increase			19

The difference between the number of pups embraced in these two counts is 19, representing an increase in 1909. This indicates that practically no change has occurred in the numbers of cows on this rookery between the years 1908 and 1909.

St. George Island.—A count of pups was made in 1909 on North rookery on St. George as has been done for several years.

COUNTS OF PUPS ON ST. GEORGE ISLAND, 1908 AND 1909.

Year.	Rookery.	Live pups.	Dead pups.	Total.
1909	North	3,679	105	3,784
1908	do	3,969	154	4,123
	Decrease			339

The count for 1909 shows that a decrease has occurred in the number of pups on that rookery since 1908 amounting to 339, or 8 per cent.

Using the same methods as were employed in determining the average harem on St. Paul Island, it is found that the average harem on North rookery, St. George Island, in 1909 was 34.7 (109 harems, 3,784 cows).

Had the pups on other rookeries on St. George Island been counted, a different average harem would have been obtained. While North and Staraya Artel rookeries have remained practically stable in numbers for several years, the area covered by the breeding seals on Zapadni, St. George Island, is less this year than formerly, in addition to which only 1,100 cows were counted there at the height of the season of 1909, whereas over 1,500 were counted there on the same date in 1906. This shows that a decrease in breeding cows occurred there during that period. So also those counts of cows on East rookery have shown a steady diminution. If, therefore, the estimate of the average harem on St. George had been based upon counts of North and Zapadni or North, Zapadni, and East, it is certain that a different result would have been obtained.

For the last three years, however, it has been the practice to count only Ketovi rookery on St. Paul and North rookery on St. George to obtain an average harem to be used for purposes of estimation. Should we discard this method in 1909 there would be no opportunity to make a comparison between this and preceding years. For comparison, therefore, the pup count of Ketovi on St. Paul and of North on St. George will be used to determine the average harems of both islands to compute the number of breeding cows. The average harems on those rookeries, as already stated, are Ketovi, 34.1; North, 34.7.

It can thus be seen that the average harems on these two rookeries which have been accepted heretofore as typical of all differ but slightly in the size.

NUMBER OF BREEDING COWS.

It was found that there were 1,071 harems on St. Paul and 267 on St. George. Applying the average harems above mentioned to the whole number of harems on the two islands, we have the following as an estimated census of breeding cows:

ESTIMATED NUMBER OF BREEDING COWS, 1909.

Island.	Average harem.	Total harems.	Whole number of breeding cows.
St. Paul	34.1	1,071	36,521
St. George	34.7	267	9,265
Total		1,338	45,786

Contrast with 1908.—Using the rookery of Ketovi as typical of conditions on the whole of St. Paul Island, we may contrast the estimate of cows given above with that made by the same method in 1908.

In that year Ketovi contained 48 harems and 1,960 pups, affording an average harem of 40.8. As 1,062 harems were found on the entire island, the application of the average harem of 40.8 would produce a total of 43,329 breeding cows. On St. George, the typical rookery, North, had 94 harems and 4,123 pups, giving an average harem of 43.8. As there were 241 harems on the entire island, an estimate of the entire number of breeding cows on that island, based upon the average harem obtained as above, would give 10,555. For the two islands, therefore, in 1908, by the methods of estimation outlined above, there was in 1908 a total of 53,884 breeding cows.

Since 45,786 cows were estimated to be present in 1909 and 53,884 in 1908, it would appear that a decrease of 8,098 cows, or 15 per cent, has occurred during the year.

DIFFERENT BASES OF ESTIMATION.

This estimate of breeding cows, as has been stated, is based upon the size of an average harem obtained by counting the pups on only one rookery on each island. It may be granted that had another rookery on either island been selected as typical an entirely different result would have been obtained. This may be seen readily by a scrutiny of the average harems on the various rookeries on St. Paul on which pups were counted in 1909. As it is, the Ketovi rookery average harem of 34.1 represents a fair mean between the highest and the lowest averages obtained by counting other rookeries, and might fairly be taken as typical of the entire island when considering the size of the average harem. The fact that the average harem may be made to vary greatly by the selection of other rookeries is cited, however, to show that the estimate made is open to criticism on the ground of uncertainty as to its accuracy. If, instead of constructing an estimate based upon an average harem and contrasting that estimate with one made in the same manner the previous year, we were to take the percentage of decrease shown by an actual count of pups on certain rookeries, it is believed that a more accurate idea would be obtained as to the changes occurring in the breeding cows.

In observing the decrease in seal life it has appeared that certain rookeries, or rather portions of rookeries, either show a smaller rate of decrease than others or in some instances do not show any decrease at all, while others do. We may take it from this that certain localities are focal points in the breeding areas, attracting the breeding

seals more than others. Around these central points the animals gather instinctively, while those that can not obtain lodgment thereon spread to one side or the other. So, also, when the rookery space occupied retracts by depletion of the herd the spaces on either side of these focal points are first deserted and the herd converges upon the places which seem most desirable as breeding grounds.

Owing to the decrease in the herd during the last few years, opportunity has been offered to ascertain the points more desired by breeding seals. On these places the diminution has been less apparent than at others, or the diminution between particular years has amounted to nothing at all. We have seen that Ketovi rookery for several years has shown scarcely any loss, while portions of other rookeries have been virtually eliminated or reduced to skeletons of their former aspect. Lukanin rookery, for instance, immediately adjacent to Ketovi, has had four-fifths of its breeding area denuded, and such breeding seals as are left gather only on the hill at the southern extremity. Portions of Gorbatch rookery are deserted, leaving such seals as are there at the central portion, approximately, and the extreme west end. Polavina rookeries have retracted until practically all seals are at Polavina Point. Northeast Point rookery has retracted from the ends toward the center. Zapadni rookery has receded toward its central massed areas, leaving the bowlder beach line of Zapadni Reef almost bare of seal life. Ketovi rookery itself has abandoned that portion which abuts Black Bluffs, but after rounding Ketovi Point the breeding seals there seemed to have maintained their numbers with little or no decrease.

Likewise, on St. George Island, North rookery seems to be a favored spot that attracts breeding seals to the exclusion of other rookeries. It has shown little decrease, or rather a more gradual decrease than East rookery and its outlying areas and Zapadni rookery, which seem to have suffered such loss in breeding seals as has occurred on St. George in recent years.

It can be seen, then, that the loss among breeding seals is greater in some areas than others, and that the least decrease has occurred on Ketovi and North rookeries, the ones chosen as typical. Since this is the case it would seem proper that the loss in seal life should be sought where it really occurs and not upon those rookeries that are shown to have remained stable in numbers or on which the rate of decrease is slower than upon others. Consequently, judgment as to the condition of the rookeries in general should be based not upon conditions on one rookery alone and upon that rookery in particular which shows least change. The data upon which it is to be formed should be gathered from other localities as well upon which changes have occurred. Only in this way, in my belief, can a correct idea be formed as to changes in the number of seals present. It would,

of course, involve extended counting and this means unwonted disturbance of the breeding cows. For this reason it should not be done every year. But at intervals of five years, for example, an extended count of pups should be made on each island and from the data thus obtained should be made an estimate of the number of breeding cows in the herd.

Disturbance of the rookeries in itself means no harm, provided it is not constant. No harm to the cows follows directly from the act of their being disturbed and driven off their breeding ground. Harm does come, however, when such driving occurs in connection with the presence of over 100 small boats filled with men armed with shotguns, waiting as close to shore as they may come, ready to shoot the seals that are driven off the rookeries. While such a menace is present ordinary prudence dictates that the seals on shore should not be disturbed unless it is desired to augment the pelagic catch from the breeding cows that represent the very life of the herd.

In the interval between these suggested five-year counts no serious effort need be made to count the seals. Inspection of the area occupied would disclose in a general way whether any radical change in the numbers had occurred and this could be done without disturbance. The Government could well afford to sacrifice some of its minute data regarding seal life to the greater consideration of saving the lives of many breeding cows each year by refraining from driving them within reach of the pelagic fleet.

CONCLUSION AS REGARDS BREEDING COWS.

It may be accepted as a fact that a decrease in breeding cows has occurred since 1908. The retraction of the breeding seals from the places formerly occupied and the actual count of pups on North rookery demonstrate this. The fact that Ketovi rookery on St. Paul does not show a decrease from 1908 must indicate either that the numbers on this particular rookery have been maintained through accessions of cows from other less attractive rookeries, or that pelagic sealing had less effect upon the cows frequenting this rookery than upon others.

From such data as we have on hand at present, which have already been detailed, it will be safe to conclude that the decrease in breeding cows varies between 10 and 15 per cent. It may be safe, furthermore, to estimate that the whole number of breeding cows now embraced in the herd is in the neighborhood of 45,000, varying several thousand on one side or the other because of the necessary amount of conjecture used in making the estimate.

NONRETURN OF COWS AFTER DISTURBANCE.

Upon the occasion of the counting of pups on Lagoon rookery last summer count was made of the cows on that rookery before they were disturbed and driven off by the approach of the pup counters. On that date (August 4) 320 cows were present. Daily, for a week thereafter, this rookery was revisited and the cows recounted, the object being to ascertain whether after being driven off into the water the cows returned to the rookery in anything like the number present before the disturbance.

The series of counts made justifies the conclusion that after having been so disturbed the cows do not return in the same numbers as before the clearing off of the rookery. A list of the counts of cows follows:

August 4	320
August 5	204
August 6	190
August 7	164
August 8	193
August 9	163
August 10	148
August 11	152

This shows that on the day after this rookery was first disturbed 116 cows had failed to return and in all probability had gone to sea. At no time thereafter were there as many cows found on the rookery as when they were first driven off. We must conclude from this that driving off of cows from a rookery increases the number at sea which may be killed by pelagic sealers and that, under present conditions, disturbance of the rookeries in the manner indicated has the effect virtually of increasing the pelagic catch.

CENSUS OF SEAL HERD.

In making a census of seals in the whole herd only the adult stationed bulls are actually counted, together with a small number of pups. By means of the latter an average harem is established, to be used in estimating the number of pups and breeding cows. This, however, has already been explained. All other seals in the herd can be enumerated only by estimation based upon such facts concerning their numbers as we may be able to gather.

ESTIMATE OF HALF BULLS.

Records kept of the dismissal of large seals from the killing grounds show that 1,770 large young males were turned away on both islands. Observations made heretofore by me, based upon the percentage of return of 3-year-old males, suggest strongly that not more than 50 per cent of the half bulls appeared upon the hauling grounds, the

other half hanging about the rookeries worrying the cows. This indicates that the number of half bulls appearing in the drives should be doubled in endeavoring to arrive at the whole number. If we double those seen in the drives in 1909 we would have 3,550 as an estimate of the young males in the herd too young to hold positions on the breeding rookeries, but too old to be killed for skins.

ESTIMATE OF YOUNG SEALS.

In 1907 the census of seals gave the number of new-born pups as 50,825. Of these one half were males and the other half females. These pups of 1907 would be 2-year-olds in 1909.

By the usual process of estimation the 25,000 male pups in 1907 would return to the islands in 1909 to the number of 10,165. Approximately 8,000 of these were killed by the lessee in 1909, leaving 2,165 surviving at the close of the season.

The female 2-year-olds by this process would number 10,165 in 1909.

The yearlings in 1909 would number approximately 12,000, divided equally between the sexes.

Of the 3-year-old bachelors, 1,000 were reserved for breeding in 1909. In addition to these some few escaped driving. A fair estimate of the number of this class would be 1,200.

STATISTICS OF SEAL LIFE IN 1909.

From the foregoing we may construct the following census of seal life at the close of the sealing season of 1909:

Bulls, active with harems	1,132
Bulls, idle and quitters	256
Half bulls	3,550
3-year-old bachelors	1,200
2-year-old bachelors	2,165
Yearling bachelors	12,000
Male pups	22,882
Breeding cows	45,765
2-year-old cows	10,165
Yearling cows	12,000
Female pups	22,882
Total	133,997

This total is an approximation, based upon such limited knowledge of the numbers of the seal herd as we possess. There are certain classes of seals which it is highly impracticable to count accurately, as, for instance, the entire body of the new-born pups. There are other classes impossible to count, as the yearlings, half bulls, and adult cows, some of which are always in the water. These facts all

result in forcing the enumerator of the seal herd to resort to estimation in arriving at their numbers.

The result of experience has been to show that previous censuses made in the manner adopted in 1909 have been inexact in showing fewer seals than actually were in existence. This probably will be the case with the census of 1909. It is altogether probable that the estimates of the bachelors made by me in 1909 are too low, due to the allowance of a higher death rate than actually occurs among them.

DEAD PUPS.

In October, 1908, and again in 1909, counts were made of dead pups on the various rookeries on St. Paul Island. These counts were made in some instances by myself or assistant agents and in others by intelligent natives detailed by me. The count follows:

DEAD PUPS, ST. PAUL ISLAND.

	1908.	1909.	
		Dead.	Starving.
Lagoon	4	15	
Tolstoi Cliffs	152	104	6
Tolstoi	287	440	14
Ketovi	36	77	2
Amphitheater	17	10	
Lukanin	77	117	8
Gorbatch Cliffs	1	10	1
Gorbatch	245	319	12
Ardiguen	24	33	2
Reef	701	881	24
Zapadni Reef	4	17	
Little Zapadni	183	270	6
Zapadni	309	426	18
Polavina	45	131	7
Polavina Cliffs		52	2
Little Polavina	4	36	
Northeast Point	854	722	17
Sea Lion Rock		126	6
Total	3,003	3,786	125

In 1908, with approximately 50,000 births, 3,000 dead pups were found in October of that year on St. Paul alone. What the death rate was on St. George is impossible to determine, as foxes eat the dead pups' bodies immediately after death. Furthermore, the bodies of such pups as die early in the season have, by October, almost entirely disintegrated, and can not be seen when counting is done late in the fall. In 1909, with a diminished herd of cows, more dead pups were counted than in 1908. We must believe that mortality among pups was greater in 1909 than in 1908, caused, undoubtedly, by increased pelagic sealing, and that such mortality while the pups are on land is in the neighborhood of 10 per cent.

On August 12 the dead pups on Tolstoi sand flat were counted, with a view of finding uncinariated pups. All seals on the flat

were driven off. We found thereon 271 dead pups. Of these, 151 of the freshly dead plainly were starved. Of the remainder, the most were so rotten that, not only could no dissection be made, but it was impossible to tell in any way the cause of death. Of those freshly dead, 7 autopsies were made. Three of these plainly indicated starvation, the autopsies being made merely to verify that fact. Two dead pups were found with an abundance of subcutaneous fat and with stomachs full of milk. The flesh was anemic and pale. Areas of inflammation were found in the small intestines of each. These areas were dissected, but no worms were found there. In the appendix of one of these pups, however, and in the small intestine several inches from the appendix, a number of worms from one-half to 1 inch in length and of the thickness of a thin hair was found. These were preserved, together with the entire small intestine, for further study. Portions of the intestines of all pups dissected were preserved. One pup was found which, although emaciated in appearance, was found to have a small layer of subcutaneous fat. The feces in this case were dark but not tarry in the large intestine. Another dead pup was found with pale excrescent kidneys of very irregular form. Mr. Chichester believed the evidence in this case to point to fatty degeneration. The bowels and other organs of this animal were normal.

All specimens of intestines and worms found upon this occasion were forwarded to the Bureau of Fisheries, but as yet no microscopic examination of them has been made.

As the result of the examination of the Tolstoi sand flat, it was found that over half the dead pups plainly had died of starvation; that of the remainder, which included all the wholly rotten pups, only a few were found whose death could be ascribed to uncinaria. Whatever may have been the death rate from uncinaria in previous years, it is certain that its effect at the present time is almost nothing.

EFFECT OF PELAGIC CATCH UPON LAND CATCH.

The effect of the pelagic catch is supposed to be felt directly by the breeding herd. Pelagic catches are supposed to consist mainly of breeding females. If the pelagic catch is heavy fewer females are supposed to appear on the islands; if light, more females will be present. If more females appear, the births will be increased and more bachelors be present two years later as 2-year-olds. As the lessee's catch, except for the years 1904–1908, has been composed mainly of 2-year-olds, it would be supposed that the effect of a heavy sea catch would be felt two years later in a decreased catch of bachelors on land.

An examination of the land and pelagic catches for a series of years, however, fails to show such a close connection between the land and sea catches as would be supposed. The following table contains the pelagic and land catches from 1900 to date:

PELAGIC AND LAND CATCHES OF SEALS, 1900 TO 1909, INCLUSIVE.

Year.	Pelagic catch.	Land catch.	Year.	Pelagic catch.	Land catch.
1900	35,191	22,470	1905	25,320	14,368
1901	24,050	22,672	1906	21,236	14,476
1902	22,812	22,386	1907	16,036	14,964
1903	27,000	19,292	1908	18,151	14,996
1904	29,006	13,128	1909		14,336

It can be seen from this table that a heavy pelagic catch (35,191) occurred in 1900, yet the land catch of 1902 was within a hundred of what it was in 1900. We find a heavy pelagic catch in 1903 (27,000), yet the land catch of 1905 seems not to have decreased to any appreciable extent when we consider the restrictions upon land killing in that year and the number of bachelors released for breeding. The pelagic catch of 1904 increased to 29,000, and we have found a decrease in the number of bachelors present in 1906, although this might have been merely a coincidence. We find in 1905 still a large pelagic catch (25,320), but we have already stated that the number of bachelors present in 1907 was greater than the preceding year. In 1907, on the other hand, we had a small pelagic catch (16,000), but, notwithstanding this, the number of bachelors in 1909 was smaller than ever before, when, according to theory, there should have been more bachelors present than formerly.

The effect of pelagic sealing is cumulative and twofold; it diminishes not only the number of 2-year-old seals appearing two years thereafter, but also the number of seals in general appearing during the year itself. Those females killed in the spring off the northwest coast of course do not reach the rookeries, thereby decreasing the number of breeding seals in that year. This means a decreased number of pups born and of 2-year-old seals appearing two years later, but the effect is felt also in the year in which the pelagic catch is made.

For this reason it is hard to attribute a decrease in bachelor or other seals occurring in any year specifically to the pelagic killing of any former year. Should the pelagic catches be greater the herd will decrease; if they become less the herd will remain stationary or will increase, but it is not possible, in the light of present knowledge, to trace a reduction in bachelors exactly to the pelagic catch of any one year, although the effect must be felt sooner or later.

FOXES.

ST. GEORGE ISLAND.[a]

In point of numbers the fox catch this year was extremely unsatisfactory, being smaller than at any time since 1904–5. There can be little doubt, however, that this falling off was due not to any diminution of the herd but to the peculiar conditions of the weather. There was practically no snow on the ground up to February 1, while during the latter part of November, the whole of December, and the greater part of January, the entire trapping season, in short, rain fell constantly, the beaches were open, and vast congregations of sea quail, sometimes acres in extent, covered the sea in close proximity to the land. Numbers of these birds seemed to be suffering from some distemper, which rendered them helpless, and they were cast ashore, attracting the foxes to the beach instead of to the traps for food. It was only by constant trapping that the catch was saved from utter failure.

Trapping was begun November 19, at 4 o'clock in the afternoon, and by 8 o'clock that night 234 foxes had been captured in the three traps, the largest catch handled in one night since the present method of trapping was established. Only one more large catch, of 74, was secured, however, the remainder of the total being secured in small lots. Early in February the foxes began to change color and lose their fur in spots, and on February 12 so marked had these changes become that trapping was discontinued.

During the sealing season of 1908 all the carcasses of seals killed and not consumed by the natives were salted down for fox food, the company providing the necessary salt for the purpose. The company also furnished, as required by contract, 12 tons of salted fish. In addition to this there was a large amount of salt fish on hand from previous years. This, however, was not used, nor indeed was all that was supplied this season.

The feeding of salt cod was begun October 5 and continued until November 17, when seal meat was added. During the month of October but little of the food put out was eaten. The foxes for some unknown reason do not take kindly to salted cod. This was remedied somewhat, however, by soaking a number of seal carcasses in each batch of cod, which treatment seemed to give a piquancy to the cod and render it more acceptable to the foxes. From December 28 to January 21, however, but a small fraction of the seal meat fed was eaten, and there were but very few days during the entire winter that the quantity of food put out was not in excess of that consumed.

[a] The report on the foxes of St. George Island was prepared by Mr. H. D. Chichester, assistant agent in charge of that island during the season of 1908–9.

The supply of seal meat at the village became exhausted April 9, 1909, but the feeding of cod continued daily until May 1, at which time the birds arrived in such numbers as to render further feeding unnecessary. The total amount of food known to have been consumed by the foxes is as follows:

	Pounds.
Salt cod	4,116
1,030 salt seal carcasses	25,750
Offal of 400 seals	4,500
Total	34,396

The total catch for the season was 779 blue and 10 white foxes. From these were selected for breeding purposes 198 blue males and 223 blue females, leaving 230 blue males, 137 blue females, 4 white males, and 6 white females to be killed. The foxes selected for breeding were, without exception, the finest lot that have thus far come under my notice. No male weighing less than 10 pounds was saved, and no female of less than 7½ pounds. Most of the males weighed 11 pounds or over, and by far the larger number of females tipped the scales at 8 pounds or over. No lame, blind, old, or decidedly off-color foxes were preserved. In fact, so rigid was this selection that the end of the season found the number saved for breeders considerably less than usual. This, however, seems to be of small moment, as the number of foxes that did not pass through the traps at all is this year unusually large. A dozen foxes have been counted about the village, half of which were not branded, and this seems to be about the ratio of branded to unbranded met with at various points about the island.

But two dead foxes were found during the entire year. Autopsy failed to show cause of death. About a dozen mangy foxes were observed. All of those that were caught were destroyed, and the rest unquestionably perished during the severe weather that prevailed in March and April. A fox denuded of its fur would have little chance to survive the terrible blizzards and cold of these months.

Of the 367 blue and 10 white skins taken this year the company accepted 357 blue and 10 white. Eight blue were rejected, and 2 mangy skins that were absolutely worthless were destroyed. In payment for the skins accepted ($5 for each blue and $1 for each white) the sum of $1,795 has been credited on the company's books in favor of the native inhabitants of the islands and is available for their support.

ST. PAUL ISLAND.

While a slight increase in the number of foxes on St. Paul was noted, there were not enough present to justify trapping, although the natives were anxious to get some skins and spend the cash for firearms. The increase in foxes on this island since the epidemic

of 1903 has been very slow. The fox herd here probably never will reach its former size unless such foxes as are on the island can be trained to gather at certain localities where they may be fed. Heretofore, although attempts have been made, some more or less elaborate, it was not possible to induce foxes on St. Paul to eat food thrown out for them. This being the case, they could not be gathered into herds or bodies, without which systematic feeding or trapping could not be accomplished. Last year, however, for some unexplained reason, a number of foxes gathered about the village and readily ate salt salmon freshened in pure water and thrown out to them.

On February 19 it was noted that whereas a lone fox had been acting as scavenger about the village during the winter, on that date five were seen. Thereafter more than one fox could be seen constantly. In March, owing to the presence of drift ice and zero weather, it was believed to be good policy to offer food to these foxes, and accordingly some salt salmon having been obtained, about March 25 (the exact date was not noted) some of it was freshened and thrown out. This disappeared, but rather slowly. On March 29 a second feeding was thrown out, consisting of six salmon. This was eaten. Previous to this date the quantity of food consumed each night had not been noted, but thereafter attention was paid to it. Salmon, sea-lion meat, and hog offal were supplied in varying quantities until May 17, and were each time all or partially consumed. At the latter date feeding was discontinued, as birds were in abundance and the weather mild. Foxes increased in numbers about the village after feeding was begun. As many as 15 were seen at one time on the flat where the food was distributed. This is the first time these animals could be induced to congregate about the village and accept food. Perhaps the fact that the salmon was soaked in pure water instead of in sea water, as in previous attempts, made a difference.

Further attempts will be made this winter to congregate the foxes by feeding. During the sealing season some seal carcasses were buried to be used for fox food in winter.

ADMINISTRATION OF LAWS.

PELAGIC SEALING.

The subject of pelagic sealing has been treated at such length by investigators in the past that it is needless here to reiterate statements showing its deadly effect upon the seal herd. The laws of the United States in the matter have been published in Bureau of Fisheries Document 732.

Sealing fleet and catch.—The pelagic fleet about the seal islands in 1909 was composed of 23 Japanese and 5 Canadian schooners. Of

these, 20 Japanese were boarded by our Revenue-Cutter Service on patrol and 3 additional by H. M. S. *Algerine*, assigned to the patrol by the British Government. The catch of the Japanese up to August 17, as reported to the boarding officers, was 6,610. It is believed that their total catch for the season will approximate 10,000 and be equal at least to that of 1908.

None of the five Canadian schooners which were granted licenses for sealing in 1909 were boarded by the patrol vessels after August 1, and it is believed that their operations were conducted far off the Pribilof Islands. Those that were boarded were in the neighborhood of the Semidis on June 23, when their masters stated their intention to visit the Commander Islands and later to seal in Bering Sea. As stated before, none were afterwards seen sealing by the patrol, although the *Thomas F. Bayard* put into Unalaska harbor on August 17, and her master stated his intention to seal thereafter about 200 miles north and east of the Pribilofs.

Authentic reports of the pelagic catch of 1909 are meager. No report from Japanese officials showing the 1909 catch of vessels flying that flag has been received. The United States consul at Victoria, in a telegram of November 10, last, informed the State Department that the official figures of the Canadian catch for 1909, complete, are as follows: British Columbia, coast, 1,493; outside area, 623; Bering Sea, 1,439; Indian catch, 187; total, 3,742.

To this must be added a coast catch by Indians on the coast of the United States of 411, so far as now known.

Seizures of sealing vessels.—On July 9 the revenue cutter *Perry* seized the Japanese schooner *Tenyu Maru*, having captured one of her boats within the 3-mile limit, in which boat was the body of a fur seal recently shot. The schooner was taken to Unalaska and after a preliminary hearing before the United States commissioner at that place the master and crew, 17 men in all, were bound over to the grand jury at Valdez for trial at the October session of the United States district court. They were transported to Valdez on the cutter *Perry* and given over to the United States marshal at that place on September 4 to await the action of the grand jury. The schooner was held at Unalaska.

On September 2, at Walrus Island, about 7 miles from Northeast Point, two Japanese rowboats from the schooner *Eun Maru*, containing six Japanese seamen, one fur seal, and complete sealing outfits, were seized by assistant agent Judge and natives for sealing within the 3-mile limit. These six Japanese were delivered to the revenue cutter *Bear*, which took them to Unalaska. They were tried there before the United States commissioner and each sentenced to three months in jail and a fine of $200 and costs. A failure to pay the fine and costs will extend the jail sentence to more than six

months. The prisoners, after sentence, were sent, on September 30, on the revenue cutter *Rush*, to Valdez, where their sentences will be served.

At the time of the capture the facts were at once reported to the captain commanding the cutter *Bear*, with a request that search be made for the schooner to which the boats belonged, and the apprehension of her, if found. Although both the cutters *Bear* and *Manning* afterward made such search, nothing thereafter was seen of the schooner, which clearly was liable to seizure.

Numerous instances were reported by the native guards stationed on the rookeries of the approach of small sealing boats close to shore, during the temporary absence of the patrolling cutters. On several occasions, during thick fog, the noise of the sealers' gun fire could be heard at the village plainly and almost incessantly for several days at a period. Because of the fog it was not possible to determine how close to shore the sealers were, but it is believed that they were within the 3-mile limit. On another occasion, while island boats manned by natives were fishing off St. Paul, they were surrounded in the fog by boats of the sealing fleet, the occupants of which were engaged in shooting at seals. The natives on this occasion had some difficulty in avoiding being shot by chance buckshot which were flying in all directions about them.

Locality of operation.—The sealing fleet, as heretofore, centered at St. Paul Island, to the virtual exclusion of St. George Island. Unlike last year, however, the main body of the fleet operated to the southwestward of the island, whereas in 1908 the main body of the fleet hung off Northeast Point, with only a smaller portion off Southwest Point. Several schooners remained at anchor for some weeks between St. Paul and St. George islands.

While the usual practice was for small boats to leave their vessels in the morning and to cruise all day in more or less haphazard fashion, it was noted that the crews of several adopted a much more systematic course. Their method was to ascertain the location of the 3-mile limit by bearings and to distribute themselves along this line with regular intervals between their boats. Maintaining these positions as nearly as possible, they waited for the seals to pass them while going to and from the islands. They carefully avoided entering the 3-mile limit, but they were equally careful to lie as close to it as permissible, depending upon the transit of the seals through their line for victims rather than upon their own efforts to move about in search of the seals. As seals constantly are going back and forth to and from the rookeries, it is obvious that all will be obliged to pass over the line representing the 3-mile limit. Notable among the schooners observing this method was the *Toyai Maru 2*, the crew of which in 1906 landed upon Northeast Point rookery and killed about

200 female seals. This schooner employs white hunters and uses the Japanese only for boat pullers. As the result of using only white hunters, this one vessel alone secured over 1,000 sealskins last summer.

Revenue-cutter patrol.—The patrol furnished by the revenue cutters was never before so thorough and effective as last summer. Rarely, if ever, was either island left without protection. One vessel was stationed constantly at St. George and at least one and usually two about St. Paul. The two cutters at St. Paul divided the coast line between them and each made daily cruises over its territory. In addition, one made its station at Northeast Point while the other made its base at the village, thus covering both extremes of the island. Under these conditions it was difficult for poachers to come inside the 3-mile limit except in thick fog when their movements could not be observed, and when, in fact, it is my judgment, they did enter on several occasions.

The cutters also regularly conveyed mail to and from the islands, and such island passengers as had occasion to go. I visited St. George Island on business twice during the summer, through the courtesy of the captains of the *Manning* and *Rush*, respectively.

Shore guard unnecessary.—The effective patrol maintained this summer demonstrates the lack of necessity of having a shore guard of marines in addition to that native guard already maintained by the agents. The undesirability of such guard could be demonstrated as readily.

The proposition to station sailors ashore to act as guards to prevent violations of our laws carries with it the proposition to abandon the effective patrol by the cutters heretofore maintained and to relieve these cutters of the necessity of constant cruising or, in fact, of anchoring at the islands except occasionally. Dependence would be had thereafter for enforcement of our laws mainly upon the shore guard and not upon the patrol about the islands by the cutters themselves.

To anyone familiar with the situation it is apparent that the protection of the seal islands embraces two elements, namely, first, the protection of the rookeries themselves from actual invasion, and, second, the maintenance of the integrity of our 3-mile limit. With only a shore guard stationed upon land, it is obvious that the 3-mile limit would be without protection, as the shore guard would not be upon the water, nor could it, on the treacherous shores of the seal islands, find landings when it desired to put off and apprehend marauders.

The shore-guard proposition, therefore, would amount virtually to an abandonment of the protection of our 3-mile limit and would place the situation in about the same status as it was in 1906, when

poachers could operate without interference within the limit and approach our shores at will. This situation would make a poacher of every sealer in the Japanese fleet; it would invite raids upon the rookeries themselves, and, however unsuccessful the latter might be, would provide such a source of friction between the two Governments as would constitute an ever-present menace to the stability of the good feeling now existing between them.

It would be better policy, in my opinion, to continue the expense and trouble of the maintenance of the present effective patrol than to leave the islands without protection, except on land, where summary punishment for raids could be administered. To prevent crime is better than to punish it after its commission. The present patrol now prevents invasion of our territory. To abandon this patrol and to substitute only a shore guard in its place is to remove this element of prevention and to invite violations of our laws in the hope that we might afterwards apprehend and punish the offenders.

The present shore guard of natives uses great caution in moving about the rookeries to avoid disturbing the timid bachelor seals, from which the take of skins is secured. A shore guard of marines on the rookeries, unacquainted with the habits of the seals, and unable to distinguish bachelors from breeding cows, would create and maintain such confusion on the rookeries as would seriously interfere with the securing of the normal yield of skins.

Furthermore, the presence of such a guard in the villages creates difficulties of an administrative nature which should be avoided. On the other hand, to station such a guard at or near the rookeries would occasion a constant disturbance of seal life which would be equally objectionable. I recommend that a shore guard on the islands be not permitted.

AFFAIRS OF THE NATIVES.

Census of inhabitants.—A census of the islands for the year ended June 30, 1909, showed a total native population of 280. The individuals and groups composing this total may be classified as follows:

NATIVE INHABITANTS OF THE PRIBILOF ISLANDS, YEAR ENDING JUNE 30, 1909.

Class.	Number.		Class.	Number.	
	St. Paul.	St. George.		St. Paul.	St. George.
Families	41	22	Deaths	5	5
Males	100	43	Net increase	16	
Females	93	44	Net decrease		1
Arrivals	5		Total population	193	87
Births	16	4			

Schools.—As required by its lease, the North American Commercial Company maintained on each island a school for children of the natives. The school year covered the period from September 1 to May 1, with five days of attendance each week, usual holidays excepted. On St. Paul Island the enrollment was 43; on St. George 21. Only the English language was taught, with the usual common-school elementary subjects. Except during the early part of the year, when an epidemic of mumps prevailed, the pupils were regular in attendance and made good progress.

Public health.—The general health on the islands during the year was good. An epidemic of mumps went through both islands during the fall of 1908, affecting nearly all the inhabitants, but without complications or serious effect. During the winter infants on both islands were attacked by impetigo contagioso, while the St. Paul population, including all the whites, were annoyed by scabies, or itch. This unpleasant disorder, the eradication of which requires rather heroic measures, still affects some of the St. Paul natives, who can not be prevailed upon to take the necessary arduous steps to stamp out the pest.

Earnings.—The natives on St. Paul realized during the sealing season ended July 31, 1909, $8,386.50 from the taking of 11,054 fur-seal skins, at 75 cents each, and 48 sea-lion skins, at $2 each. The St. George natives, during the same period, earned $2,485.50 from the taking of 3,314 fur-seal skins, at $2 each, and $1,795 from 357 blue-fox skins, at $5 each, and 10 white-fox skins, at $1 each. These sums, in conjunction with the appropriation of $19,500, make a total of $32,167 available for natives' support during the fiscal year ending June 30, 1910.

The amount was allotted between the two islands as follows:

285 tons coal for both islands, at $20 per ton	$5,700
St. Paul Island, 41 families	18,467
St. George Island, 19 families	8,000
Total	32,167

In the above allotment was included an allowance of $650 for the purchase of potatoes and onions for the population of St. Paul. A similar allowance was not made for St. George, as the potatoes and onions necessary for that island were paid for from a small balance of funds unexpended from the previous year.

In making the above allotment, the government appropriation was apportioned as follows:

Coal for both islands	$5,700.00
St. Paul Island, natives' support	10,080.50
St. George Island, natives' support	3,719.50
Total	19,500.00

This arrangement, after payment of fixed charges, such as coal, potatoes, and onions, etc., represents a yearly per capita allotment for the 193 individuals on St. Paul of $91.81 and for the 87 inhabitants on St. George of $91.95.

I have to report that the lessee faithfully performed all the obligations of its contract, paying especial attention to those portions thereof having reference to the care and welfare of the natives.
